>144.55.

Steve, subtract 10.7 from 144.55 and divide the remainder by 7 and you
get 19.122. The seventh harmonic of the xtal is mixed with the
incoming signal and yields a 10.7 mHz product.

UHF Power Amplifier Modules

The MITSUBISHI M67729H2 has been developed and produced in large
quantities
for UHF cellular telephone applications.

Technical Data:
Output Power = 20 W
Gain = 21 dB
Harmonics = -40 db
Spurious Outputs = -70 dB
50 Ohm in/out

This module is also excellent suited for class C Amateur Radio PA's in
the 70 cm-Band.
The low output of a UHF handheld may be amplified to about 20 W output!
The use of these modules is the easiest way to build a PA. There are
various discriptions in the ham literature.

I am now able to offer you this excellent module with a more than 10 dB!
price
reduction:

1 ea for DM 35,--
10 ea for DM 300,--

plus postage with C.O.D. charge.

>-----------------------------------
>Grant Youngman / NQ5T
>nq5t@gte.net
>http://home1.gte.net/nq5t/index.htm
>-----------------------------------

The Motorola Master Index says that a direct replacement is 1N5240A.
It says further that power rating is 250 mW and zener current is 12
mA, but it says nothing about the voltage.

1N5240A in turn says that the zener voltage is 10 volts, zener current
10 mA and power rating 500 mW.

A very good German manual says that 10 volts at 12 mA. Hope this
helps.

3197. ?3D digitizing- precision phase measurements

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-03-20 00:00:00 UTC
From: trevere@cv.hp.com
Message-ID: <E7Cq9u.EE9@hpcvusn.cv.hp.com>
Source record: 95933

Hi,

I am looking at design alternatives for a system to do 3D digitizing over
a radius of 60 feet or so with an accuracy of a few inches

The technique that I am considering now is to use
three antennas and compare the phase differences between the three for a
signal from an unmodulated carrier emitted by a mobile transmitter.

The ARRL manual has a schematic for a very-low-phase noise xtal oscillator
so I 'm assuming that I can leverage this for a source.

The receivers would consist of an omnidirectional antenna followed by a
filter(xtal- probably) & an IF amp to get adequate signal level to do the
comparison. the outputs would be fed via equal length coax into a central
detector where phase comparisons would be done between the signals.

detection possibilities I have considered are
> comparing the output from a phase locked oscillator using an ECL XOR.
(I haven't been able to identify a suitable integrated PLL, yet)
> no PLL- signal fed from limiting amp into an ECL XOR
> using an off-the-shelf detector such as the Analog Devices AD9901

The output of the detector would then be filtered with a low pass(< 10Hz)
& fed into an AtoD

Neglecting issues such as the number of measurement points needed to
eliminate ambiguity about the location of the transmitter, I would greatly
appreciate any comments about the system outlined above & other issues
such as-

> Multipath - assume a transmitter & receiver from ground level to
20 feet above

> Phase variations in a receiving chain & phase noise of IC PLLs

> Tradeoffs for the frequency used

I'm not an RF person & would greatly appreciate any pointers to help as
well as informed opinions about issues I have listed or problems not
immediately obvious to a nonspecialist.

Thanks in advance,

Good point, Rob. To make a step-start circuit work properly with dual
voltage amplifiers, it takes dual step-start resistors.
>
> I think the inrush stuff is minor compared to safety issues.
>
Whether one or two step-start resistors is used with a 240v amplifier, the
chassis is always connected to the mains-neutral. What safety issues?

Mine uses one of those 0-60sec adjustable Agastat (sp?) relays. They're available pretty cheap at flea markets, but expensive if you buy new. Then you can have any delay you want, and drive panel "STBY" and "RUN" lights with the extra relay contacts.

Otherwise with varying line conditions, temps, the delay is not very repeatable.

Rob.

> Thanks in advance.
> Claudio

Hi Claudio -- an admirable project. For the crystal detector -- try a
small whisker wire on a razor blade. It works -- I remember doing this
as a boy experimenting with xtal radios.
For the inductor we used copper wire on an oatmeal box. An improvised
slider was made to adjust the inductance. You will probably need a pair
of hi impedance headphones rather than a speaker as the resultant output
is a rather low level signal.

There is an xtal radio page which has some books and info. See my page
below and go to the index -- then xtal radios.

Good luck

> impedance loads."
>

It is possible to imagine a load impedance so low in resistance and so high in reactance, and also a tuner that is not designed to deal with it, that the efficiency can be almost nonexistent. In particular, if the circuit Q (loaded Q) is too high because of too-small capacitor values and inadequate coils at very low values of inductance, then we are using the wrong tuner for that particular difficult situation.

This situation constitutes flagrant misuse of that particular tuner design. Antenna tuners is one area where we have to be on our toes.

I do think the vendors need to specify their products more precisely, instead of just the usual hooplah advertising come-ons that we see in the ads.

First I'm no expert on this, and try to put it the way I see it.....SO..

I see in some posts here, reference to neutral and chassis ground as the same thing.

The newer books have taken into account the new wiring for neutral and ground and do not refer to them as the same.

I think in the (USA) the National Electrical Code has definded neutral and ground. They are not the same thing. They are the same at one point. The main service enterence. They are bonded together and tied to an earth ground. After this point they differ. The neutral carries the unbalanced (240vac) load current. The ground carries "fault current".

Why worry, because the wire carrying the neutral current has resistance. There for volt drop. Now some place along the system the ground (carrying no current) and the neutral are at different potentials. This may be and should be a small voltage. The ground is still at earth ground potential. The ground conductor is the one bonded to the chassis not the neutral.

If you connect the ground conductor to the neutral at some place in the system, other than at the service enterence, the load current is divided between the neutral and ground conductors in that circuit. The ground is no longer at earth ground potential. There will be voltage from ground to say a water pipe (another earth ground). This is not a good condition. Any sub-feeder(in the same building) from the main service enterence is now required to have a separate ground conductor. The neutral and ground are separate.

Well this is my $.02

:--Rich-- ag6k, 805-386-3734

Rich,

I don't think most of these people have ever built anything, let alone a high power amp. I have some 4x6 glossies of my amp and power supply, which I will try to attach as JPEG's to an upcoming post. My baby took my 9 months to build:

I bought the 5kvac @1a CT transformer at Haltek in Mountain View, CA. Came out of some BC-xx AM transmitter. paid $200

8877 from that tube guy on McArthur Blvd in Oakland. paid $250

Got both 2000pf @5kv and 500pf @15kv from surplus place in Sacramento for $75, oh my god what a deal.

Chimney for 8877 at Foothill College Hamfest (Mar-Oct?) for $5

Pi Inductor specially made by B&W, the low plate Z version, took me 4 mos to get it.

Chassis/cabinet were bought new from Halted Specialties in Santa Clara, got both for about $200.

Filament transformer is 7V from Halted special $5 computer power supply sale. Use 150W adj pot for filament inrush protection and adj voltage.

I use 5A @ 7.5kv SEMTECH rectifiers in series, all bought at Halted Sp.

In summary, if you want to build amps, move to Cal. I now live in Oregon. It may as well be Libya, as far as parts procurement goes.

Rob.

3208. Chinese vs. American Tubes?

Newsgroup: rec.radio.amateur.homebrew

:
:
:Rich,
:
:I don't think most of these people have ever built anything, let alone a
:high power amp. I have some 4x6 glossies of my amp and power supply, which
:I will try to attach as JPEG's to an upcoming post. My baby took my 9

:months to build:
:
:I bought the 5kvac @1a CT transformer at Haltek in Mountain View, CA. Came
:out of some BC-xx AM transmitter. paid $200
:
:8877 from that tube guy on McArthur Blvd in Oakland. paid $250
:
:Got both 2000pf @5kv and 500pf @15kv from surplus place in Sacramento for
:$75, oh my god what a deal.
:
:Chimney for 8877 at Foothill College Hamfest (Mar-Oct?) for $5
:
:Pi Inductor specially made by B&W, the low plate Z version, took me 4 mos
:to get it.
:
:Chassis/cabinet were bought new from Halted Specialties in Santa Clara, got
:both for about $200.
:
:Filament transformer is 7V from Halted special $5 computer power supply
:sale. Use 150W adj pot for filament inrush protection and adj voltage.
:
:I use 5A @ 7.5kv SEMTECH rectifiers in series, all bought at Halted Sp.
:-------------
:
:In summary, if you want to build amps, move to Cal. I now live in Oregon.
:It may as well be Libya, as far as parts procurement goes.
:
:Rob.

:out of some BC-xx AM transmitter. paid $200
:
:8877 from that tube guy on McArthur Blvd in Oakland. paid $250
:

:Got both 2000pf @5kv and 500pf @15kv from surplus place in Sacramento for
:$75, oh my god what a deal.
:
:Chimney for 8877 at Foothill College Hamfest (Mar-Oct?) for $5
:
:Pi Inductor specially made by B&W, the low plate Z version, took me 4 mos
:to get it.
:
:Chassis/cabinet were bought new from Halted Specialties in Santa Clara, got
:both for about $200.
:
:Filament transformer is 7V from Halted special $5 computer power supply
:sale. Use 150W adj pot for filament inrush protection and adj voltage.
:
:I use 5A @ 7.5kv SEMTECH rectifiers in series, all bought at Halted Sp.
:-------------
:
:In summary, if you want to build amps, move to Cal. I now live in Oregon.
:It may as well be Libya, as far as parts procurement goes.
:
:Rob.

Subject: Ground Rod Installation w/pipe

R. L. Measures wrote:
> ....snip....
> The antenna-ground on my 3/8 wave 80m vertical antenna is about 100 feet
> away from the NEC- 'ground' on the Neutral wire at my service-entrance.
> Connecting a wire between these two grounds would seeming be
> electrical-lunacy. .
> The "wire" between the two grounds in your case, Rich, is the shield of your coax. I lost 150 feet of RG-213 in this manner. The shield of your coax is connected to your antenna-ground, is it not? The other end of the coax shield is connected to the chassis of your radio. The green wire in your a.c. power cord goes from the chassis of your radio to the NEC ground bus in your service entrance panel, which is strapped by a big wire to the neutral bus in the panel. You have bonding of both ground systems whether you want it or not via the coax. The NEC requires that all antenna system, cable TV system, water well pumps, and other electrical devices all be bonded to the service entrance ground. Someone wisely stated in an earlier post that an insurance adjuster can make life very miserable for someone who ignores NEC guidelines.

Subject: Home Made "crystal' for receiver

During the war,(WWII) soldiers indeed made home-made "crystal" radios using household parts. The "crystal" was made from a blued-steel razor blade and the whisker was the "lead" (actually carbon) from a pencil. A sweet spot was found by probing around on the blued surface with the pointed end of the pencil lead. One wire went to the razor blade and the other to th pencil lead. Don't know about the earpiece or headset though. I made a carbon microphone one time using carbon from a zinc-carbon flashlight battery, a soda bottle cap for the button and a paper cup for the diapragm and housing. Maybe if you "borrow" the earpiece from a telephone handset, that will meet you goal of not going to the radio store.

By the way the "crytal" radio I described is commonly called a FOXHOLE RADIO because that's where they were used.

Good Luck DE George Dowell K0FF/7

VE3ERP has a shareware program out that does this among about a hundred other things. I am not sure exactly where to find it. If you look in ham software archives you should be able to find it. Use Yahoo or HotBot to search it should point you in the right direction.

From: trouts1@aol.com (Trouts1)
Subject: Of T368 interest only

68 owners,
I have found that some T368 owners have common problems that would seem to be in all rigs. As it turns out other owners do not have the same
problems. A few examples are problems with the vaccum relay for T/R switching on E and F models. Another is a sharp point near the final tank coil which causes arcing which is cured with filing.
I have receintly found out that there were several (if not more) manufactures
of the T3. The problems may be due to design or specification latitude where
manufactures introduces differences or the design may have changed slightly
from order to order. I decided to track some T368's with their order numbers
to see if anything common shows up as common. So I am requesting T3 owners to send me their TYPE, SR #, ORDER # and MANUF. to see what the contract span was and how SR #'s were issued. If you have time please
include what you may have problems with or any other information you may know.
So far I have only been able to locate informaiton about the T3 A,B and C
models. Fair included one E schematic in the A,B and C package they sell.
I would like to purchase manuals for the other models if anyone has them.

I have been told that the Gov't has not released the manuals past the C model.
It may be that there was not manual for the E and F. Thay may have been covered by addendiums or bullitans? If anyone has any information please let me know.
Please send any infomation you have to me at:
trouts1@aol.com and CC
davidk@artax.webo.dg.com
If there is enough enformation to be interesting I will see if ER is interested in
posting it. I will keep a list of people who respond and will send you the
compilation as it develops.

From: jstroppe@uhl.uiowa.edu (John Stroppel)
Subject: Soft-start circuits

First I'm no expert on this, and try to put it the way I see it.....SO..

I see in some posts here, reference to neutral and chassis ground as the same thing.

The newer books have taken into account the new wiring for neutral and ground and do not refer to them as the same.

I think in the (USA) the National Electrical Code has definded neutral and ground. They are not the same thing. They are the same at one point. The main service enterence. They are bonded together and tied to an earth ground. After this point they differ. The neutral carries the unbalanced (240vac) load current. The ground carries "fault current".

Why worry, because the wire carrying the neutral current has resistance. There for volt drop. Now some place along the system the ground (carrying no current) and the neutral are at different potentials. This may be and should be a small voltage. The ground is still at earth ground potential. The ground conductor is the one bonded to the chassis not the neutral.

If you connect the ground conductor to the neutral at
some place in the system, other than at the service enterence, the load current is divided between the neutral and ground conductors in that circuit. The ground is no longer at earth ground potential. There will be voltage from ground to say a water pipe (another earth ground). This is not a good condition. Any sub-feeder(in the same building) from the main service enterence is now required to have a separate ground conductor. The neutral and ground are separate.

Well this is my $.02

Subject: Tone Burst Generator

I just got to Europe and my Yaseu FT470 does not have the tone burst
generator needed to open repeaters and I'm not good at whistling.
Anyone have a schematic for a 1750 Hz tone burst generator?

Thanks in advance, WA7NPP/HB9

> impedance loads."
>

It is possible to imagine a load impedance so low in resistance and so
high in reactance, and also a tuner that is not designed to deal with it,
that the efficiency can be almost nonexistent. In particular, if the
circuit Q (loaded Q) is too high because of too-small capacitor values
and inadequate coils at very low values of inductance, then we are using

the wrong tuner for that particular difficult situation.

This situation constitutes flagrant misuse of that particular tuner design. Antenna tuners is one area where we have to be on our toes.

I do think the vendors need to specify their products more precisely, instead of just the usual hooplah advertising come-ons that we see in the ads.

Subject: Want Camcorder for ATV use - cheap

Best of luk! I finally got one... From a friend who repairs them "on the side". Checking with major chain store electronics sections for returns was an excersise in futility.... The will destroy "non-reparable" units before giving or selling. Smaller independent repair shops might help, but I was not successful. Another suggestion... Insurance companies (if you are on good terms w/agents) which paid for new and have old broken unit. The tape "basket" was dead in the one I did find, so I pulled it out and put a 900 MHz FM transmitter in its' place. Switch selects that (900 FM) or video out to separate 426 AM tx.
Woody

3226. Re: Tone Burst Generator

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-03-21 00:00:00 UTC
From: Leon Heller <leon@lfheller.demon.co.uk>
Message-ID: <npQ9cBA30sMzEwSQ@lfheller.demon.co.uk>
Source record: 95812

In article <3331A8C6.7165@ge.maxess.ch>, Gene Neill
<gneill@ge.maxess.ch> writes
>I just got to Europe and my Yaseu FT470 does not have the tone burst
>generator needed to open repeaters and I'm not good at whistling.
>Anyone have a schematic for a 1750 Hz tone burst generator?
>
>Thanks in advance, WA7NPP/HB9

You need a 4060 CMOS divider IC, which contains an inverter that can be
used as an oscillator. Pin 16 is +5 to +15V. Ground is pins 8 and 12.
Take the output from pin 14 via a 100 - 270K resistor. A 455 KHz ceramic
resonator goes across pins 10 and 11, with a 1M resistor across it. Both
ends of the resonator are connected via 1n capacitors to ground.

Leon

Source record: 95819

Argh !
where can I find some info on the M67711 module from Mitsubishi ?
Its supposed to be SHF and more than 10W.
Will it handle class AB ?
Do I need more than one DC feed (for class AB or just during TX) ?

Source record: 95820

Well, for what it's worth....

Back a couple months ago, we had the mobile TV truck over at our Gym for a basketball game. We plugged into a service outlet on the outside of the building. We ran camera cables inside, intercom cables, video for the announcers booth, audio back down from the announcers booth, you get the idea.... Well the monitor that the announcers had was a 117VAC grounded plug. We plugged the monitor into a outlet in the announcers booth instead of running AC all the way up to it from the truck. Well, as it turns out, and no one knew this, the whole ground system inside of the gym was not bonded to neutral or the ground rods at the service entrance. A transformer shorted in one of the lights inside of the gym and was putting 600VAC on the whole ground system. The outlets we were plugged into on the outside of gym were grounded. When the monitor was plugged in, a ground fault breaker opened. The engineer who was working the truck that night didn't know what was happening and why the ground fault breakers in the truck kept opening. He unhooked the video and audio lines to the announcers booth. Presto, no breaker opening up. He reached over and started to grab the video line with one hand while his other hand was pressed against a tape machine (case grounded of course), he was knocked out backwards of the truck, blacked out when his head hit the ground. He had holes in 3 fingers that touched the video connector. And if all than wasn't enough, he had a heart pacemaker. He lived and is doing fine, fingers healed, no problems with his pacemaker. We now call him LUCKY.

Is there a need for the ground separate from the neutral? Well the system that was supposed to prevent this, was actually worse than if we had no ground at all. This was a electrical problem that should have been caught when the building was constructed. Times past we plugged into the outlets and had no problems, why, because the transformer was not shorted to ground. It's amazing someone didn't get killed. The ground and neutral have to be bonded together at the service feed point for the ground safety system to work, otherwise you are better off without it. People who work in the electronics industry naturally 'assume' that ground is ground. That's a deadly assumption.

My $0.02 worth as well.

• Unlike DC coil relays, AC coil relays are not very satisfactory for
step-start service because they do not close positively when they reach the
pull in voltage.
IMO, it would be preferable to connect a small transformer to the primary
of the HV transformer. The secondary of the small transformer is
rectified, filtered, and used to power the DC coil of the step-start relay.

The step point can be contolled by placing resistance in series with the
relay's coil.

I always thought that "homebrew" was a silly word to use in the
electronics field. Homebuilt would make a lot more sense and eliminate
this confusion with the homebrewing of beer and spirits, IMHO.

The "gotcha" on using a razor blade for the detector is it had to be a
"Blue Blade" (Gillette, if I recall.) These were coated (anodized?)
with a material that would behave as a rectifier. The connection could
be made via a wire wraped around a sharpened pencil lead. They probably
don't make these blades any longer :(

Regards,
Rolf

>
no it isn't. the same way you may let a non licensed person talk on your radio while you are there with them, you may allow vhf only hams to talk on 10m thru your repeater. my license class is general and i am the control operator of my multi-cast repeater system, be it remotely or right there sitting by it. when a tech comes in on 440mHz or 6m, they are repeated out on 440mHz, 6m AND 10m simultaneously. this has been accepted and legal practice for years now. techs can even use my remote base and go way down on the hf bands because I, the control operator have the priveleges. just like at field day, the club uses the highest class license in the group and everyone id's with that call sign and so on. the repeater let's me be a remote control operator rather than sitting next to the tech "holding their hand"

hope this clears up the crossband on a repeater system thingy. a few others have said the same thing, i just took up more room yakking.

 Amen, Tom. The fault I limiting R belongs in the positive HV circuit
after the filter capacitor. For Class AB2 g-g amplifiers, the only path
from HV negative to ground should be through the grid current meter and the
paralleled glitch protection diodes.

Source record: 95877

Best of luk! I finally got one... From a friend who repairs them "on the side". Checking with major chain store electronics sections for returns was an excersise in futility.... The will destroy "non-reparable" units before giving or selling. Smaller independent repair shops might help, but I was not successful. Another suggestion... Insurance companies (if you are on good terms w/agents) which paid for new and have old broken unit. The tape "basket" was dead in the one I did find, so I pulled it out and put a 900 MHz FM transmitter in its' place. Switch selects that (900 FM) or video out to separate 426 AM tx.

During the war,(WWII) soldiers indeed made home-made "crystal" radios using household parts. The "crystal" was made from a blued-steel razor blade and the whisker was the "lead" (actually carbon) from a pencil. A sweet spot was found by probing around on the blued surface with the pointed end of the pencil lead. One wire went to the razor blade and the other to th pencil lead. Don't know about the earpiece or headset though. I made a carbon microphone one time using carbon from a zinc-carbon flashlight battery, a soda bottle cap for the button and a paper cup for the diapragm and housing. Maybe if you "borrow" the earpiece from a telephone handset, that will meet you goal of not going to the radio store.

By the way the "crytal" radio I described is commonly called a FOXHOLE RADIO because that's where they were used.

Why do you insist on posting binaries to a newsgroup so that it slows up
my incoming news for 10 mins to download this rubbish. Use a web page or
email me to a user but don't inflict it on evrybody esle. It shows a
total disregard for everyone

Hi Rob,

Part of the problem (and blessing) of written comminiucations is is
does not carry any tone. The reader can put any inflection he likes
into the words.

I was trying to congratulate you on your project, since you seemed to
be bubbling over with enthusiasm now that you finished it (and
couldn't wait to show us pictures).

In trying to understand your reply, I re-read your post.

I wonder what makes you think others "probably haven't built anything"
and also why we aren't allowed to talk about theory or safety issues?

Do you think safety issues are out of place?

You've posted to the wrong newsgroup in error. This group is "devoted" to homebrew of the radio electronic sort.

Not to worry, you're not the first.

BTW, I've never heard of Humboldt (I'm in Ontario) and I have been known to whip up the odd batch of homebrew (and drink it too!)

Tom:

Got the 95 handbook out and it appears your right. It is a bad pratice to do this with the ground and neutral. That was what I was tryiung to bring out in the post. Even to refer to them as the same thing.

But if both the neutral and the ground open somethings going to be hot thats not suppose to. You have got no saftey if both break. And RF by-pass capacitors at line frequency pass enough current to get you shocked real good if those are the only thing between the hot,neutral, and ground.

> >

This sounds like it came from the RSGB Microwave
Handbook (3 volume set), not an ARRL publication.

The ARRL publishes a UHF/Microwave Projects Manual,
as well as a UHF/Microwave Experimenter's Manual.
We also publish the proceedings of several conferences.

The VHF/UHF DX Book now published by the
RSGB is really the 2nd printing of the book
originally published by DIR Publishing.

The RSGB VHF/UHF Manual seems to have gone
the way of the ARRL's The Radio Amateur's VHF
Manual--now out of print. The latter is
particularly dated--the last printing appears
to have been in 1972. I think a modern up to
date VHF Manual is a great idea--anyone want
to write one?

John, If you look at the 95 Handbook, they return filament transformer
and other leads to the chassis in some PA designs, that is a bad idea
and against wiring standards.

If the neutral and ground lead should ever break or become
disconnected, the chassis would be hot with 120 VAC.

If you look at the two HV power supplies by Mark Wilson, neither has a
chassis safety ground. Not a good idea.

If you look at the B- return, it is clampd through a resistor to the
POWER line neutral in one supply, not a good idea.

If you look at the B- returns, they are clamped only by a resistor,
not a good idea (since a fault can force the negative lead to full
supply voltage as the capacitor discharges).

IMHO, a Handbook should contain SAFE designs.

Paul

Don"t bother with the original equp. choke. It is a B&W 800 and is
not the best choice.

Go to Peter Dahl. He has a heavy duty choke for this amp. It will
giove you no trouble at all and you will find a lot of problems from
internal arcing will go away.

The activation or "capcode is a 7 digit number also printed on the back
of the pager itself. A few companies provide demo software for computer
paging and can be found on the web.

Rich,

I don't think most of these people have ever built anything, let alone a high power amp. I have some 4x6 glossies of my amp and power supply, which I will try to attach as JPEG's to an upcoming post. My baby took my 9 months to build:

I bought the 5kvac @1a CT transformer at Haltek in Mountain View, CA. Came out of some BC-xx AM transmitter. paid $200

8877 from that tube guy on McArthur Blvd in Oakland. paid $250

Got both 2000pf @5kv and 500pf @15kv from surplus place in Sacramento for $75, oh my god what a deal.

Chimney for 8877 at Foothill College Hamfest (Mar-Oct?) for $5

Pi Inductor specially made by B&W, the low plate Z version, took me 4 mos to get it.

Chassis/cabinet were bought new from Halted Specialties in Santa Clara, got both for about $200.

Filament transformer is 7V from Halted special $5 computer power supply sale. Use 150W adj pot for filament inrush protection and adj voltage.

I use 5A @ 7.5kv SEMTECH rectifiers in series, all bought at Halted Sp.

In summary, if you want to build amps, move to Cal. I now live in Oregon. It may as well be Libya, as far as parts procurement goes.

John, If you look at the 95 Handbook, they return filament transformer and other leads to the chassis in some PA designs, that is a bad idea

and against wiring standards.

If the neutral and ground lead should ever break or become
disconnected, the chassis would be hot with 120 VAC.

If you look at the two HV power supplies by Mark Wilson, neither has a
chassis safety ground. Not a good idea.

If you look at the B- return, it is clampd through a resistor to the
POWER line neutral in one supply, not a good idea.

If you look at the B- returns, they are clamped only by a resistor,
not a good idea (since a fault can force the negative lead to full
supply voltage as the capacitor discharges).

IMHO, a Handbook should contain SAFE designs.

Wow! An 8877, that's a **big** tube.

And in only nine months!

The L200 may be worth a look. I use it in a 12V/25A homebrew power supply and have had no trouble with RFI. The L200 has current limit capability if you want to use it (I don't). You'll need external transistors to boost current handling though.

On the subject of crowbars...mine has the thyristor short the supply at the collectors of the series pass transistors. It has a resettable breaker between the capacitor bank and the collectors of the pass transistors.

When the crowbar comes in, the charge in the capacitor bank pops the breaker, thus avoiding a high shorting current through the pass transistors. Crowbar sensing of course takes place from the supply output through a 13V dropper zener diode back to the thyristor.

The breaker also acts as short circuit protection. I recommend a crowbar if you are planning on running something expensive off it. Hope this helps...good luck.

Wilbert, ZL2BSJ/PA3EYI

I posted this somewhere and forgot what news-group it started..

The 3-500 AC wiring...in the ARRL Handbook. I couldn't even
figure out what they were saying to comment on it...

Quote---- 1995 ARRL Handbook - 1995, page 13.36, fig 13.37

"Chassis ground is not equivalent to the ac-line ground.
The ac neutral wire is connected to chassis ground, so the chassis
must be isolated from the equipment cabinet, which must be connected
to the ac ground conductor"

Not just ac but there's 3 0r 4 kv going to this box....

Get an extra copy of the Handbook, so your widow can give it to
her lawyer....

Or does the membership jump up and force the ARRL to print in
big red letters on the cover....

There are some real stupid mistakes in this book and you will kill yourself, if you follow these designs.

For those who are interested in the discussion I have uploaded Part 14! to
my home page web side:

http://www.av.qnet.com/~kn6dv

Looks like things are slowing down so this might be the last upload, I will
leave this archive on the web till after Dayton and maybe I can transfer it
to some FTP side for down loading.
Thanks 73 Will KN6DV

The chemical used for bluing is selenium sulphide. So what you had was
a selenium rectifier.

This is a multi-part message in MIME format.

Hi,

Are there a lot of hams working with 9k6 packet radio with a modem like
a baycom one for 1k2 ?

It that working on a 486dx2 66Mhz ??

And where can i get the software ??

Cu adriaan

Radioamateurs in Apeldoorn

Welkom op de site van radioamateurs in Apeldoorn. Nieuw is het geluid wat te horen is aan het einde
van deze pagina. Laat eens horen wat jullie er van vinden. En vooral in welke mode er een test gemaakt wordt.
Ook het VHF nieuws is weer aangepast, met het laatste VHF nieuws en tevens
informatie over meteorenscatter en contesten en bakens. Kijk vooral naar de bakenlijst
die aangepast is aan het nieuwe band plan op tweemeter. Daar zijn de nieuwe frequenties te vinden van,
niet alleen de Nederlandse bakens, maar ook van die in het buitenland staan opgesteld. Ook de
site van de Veron afdeling Apeldoorn is update gemaakt. Met daarin activiteiten als vossenjachten,
lezingen, bestuursmededelingen, repeaters en het nieuws uit de uitzendingen van PI4APD. En tevens
zijn daar een aantal fotoboeken te vinden oa de velddag en de verkoping.

De lijst van Radio activiteiten in Apeldoorn

Veron afdeling 05 Apeldoorn

VHF nieuws

Dit is Jos PA3GXM

Dit is Adriaan PE1KHP

Dit is jamboree on the air in Apeldoorn

Digitale stad Apeldoorn

Meer Radioamateur links in de wereld

Elke reactie is welkom, dit alleen nog per email. Ook foto's zijn erg welkom in jpg formaat.
Dit voor andere achtergronden of als versiering van deze pagina's.
Vooral van bijzondere stations zoek ik nog foto's, zoals omzetters-, baken-, contest staions.

Cuagn Adriaan.

Probably,

e.c.w. = enamelled copper wire
t.c.w = tinned copper wire

Did the book say swg (standard [British] wire gauge) or awg (American gauge)?

>
no it isn't. the same way you may let a non licensed person talk on your radio while you are there with them, you may allow vhf only hams to talk on 10m thru your repeater. my license class is general and i am the control operator of my multi-cast repeater system, be it remotely or right there sitting by it. when a tech comes in on 440mHz or 6m, they are repeated out on 440mHz, 6m AND 10m simultaneously. this has been accepted and legal practice for years now. techs can even use my remote base and go way down on the hf bands because I, the control operator have the priveleges. just like at field day, the club uses the highest class license in the group and everyone id's with that call sign and so on. the repeater let's me be a remote control operator rather than sitting next to the tech "holding their hand"

hope this clears up the crossband on a repeater system thingy. a few others have said the same thing, i just took up more room yakking.

Subject: need short range xmitter design for packet

I'm looking for a good xmitter design to use for packet radio data. The range needed is about 100 meters. Small size and current use are the primary requirements.

Any ideas?

Hi!

I'am not sure you've had any reply on your question?
The TIC108 is a 50hz-scr and the characteristics depend on
the letter it ends with, A-Y
Hope this helps.

3285. Screen supply

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-03-22 00:00:00 UTC
From: Bj&#65533;rn S&#65533;derholm <sm2gxn.soederholm@boden.mail.telia.com>
Message-ID: <33346396.2F6A@boden.mail.telia.com>
Source record: 95763

Hello everybody!

I've built a amplifier with a pair of 4x500 tubes for several years ago,
and it is grid driven. A good friend of mine told me how to fix the
screen supply voltage in a way i've never heard before, now i use a
seperate stab supply for the screen. Thing is that i did not quite
understand all of it, he promised to send me a schematic digram over the
circuit, but he has probably forgotten it.
He said that you rectify part of the rf double or triple and fed it to
the screen grid. And the big advantage was that the amplifier became much
easier to drive.
Could this really be something, unstabilized screen supply?
Any thing on the subject will be greatly appreciated whether it come to
ng or my e-mail adr.

Thank's in advance!

Bjorn/sm2gxn

major snip or two

I read something years ago about lead sulfide (?) crystals, being made
with plumbers lead and powered sulfer and a short chunk of 3/8 or 1/2
inch copper pipe. You melted this witches brew together and poured it
into the copper pipe, then cut it in half part way and broke it the rest
of the way off, leaving a ragged surface. Now,,, I have no idea what
the ratio was but it didn't seem like a really big problem at the time.
Let's see,,,, if you've never melted sulfer, or lead,,,,,,,, ah hell,,,
your on your own,,, sufice to say, bad things could really happen.

3288. NOAA WX Warning Alarm Tone

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-03-22 00:00:00 UTC
From: jeffreyh@Hawaii.Edu
Message-ID: <5h1roi$oc1@news.Hawaii.Edu>
Source record: 95766

A few weeks ago I posted a note regarding the use of a 567 chip as a 1050 Hz tone decoder, the tone the WX service uses prior to broadcasting a WX warning. One person mentioned that due to EAS replacing EBS, the 1050 Hz tone will no longer be used. To confirm this I called NWS Honolulu - they were unsure, so I then emailed Stan Harter of Calif. OES; he in turn forwarded my query on to NWS Sacramento. Below is the response I received from them.

The upshot is that if you've got a NOAA WX radio with 1050 Hz decoder it will *not* become obsolete anytime in the near future.

Jeff KH2PZ / KH6

Subject: 1050HZ Warning Alarm Tone
From: Larry Krudwig at W-CR-CRH
Date: 3/3/97 7:46AM
To: Thomas Heffner at W-PR-HUB
To: Myron Kerner at W-PR-HUB
cc: Rodney Becker at W-OM14
cc: Myron Berger at W-OM14
cc: Stanley Johnson at W-OSO17
cc: Kenneth Putkovich at W-OSO17
cc: harters@oes.ca.gov at EXTERNAL
cc: jefferyh@hawaii.edu at EXTERNAL
Subject: 1050HZ Warning Alarm Tone
Tom and Myron, a message was relayed to me concerning a comment by someone in the in NWS in Hawaii that once EAS was fully operational and NWR-SAME fully up and running that the NWS would discontinue the use of the 1050Hz warning alarm tone. If indeed that comment was made or someone in the NWS believes it, that is wrong. The 1050Hz Warning Alarm Tone (WAT) will continue to be used probably forever.

There are millions of comsumer and industrial grade receivers in the hands of the public and many institutions. They will continue to be made and sold in very large quantities. I know for a fact that Radio Shack, Maxon, and Midland plan to make and market these radios for the foreseeable future.

Many models of Citizen's Band (CB) receivers on the market now have a WAT feature built into the unit. You can be monitoring any CB channel and if the WAT is detected on the weather radio channel you have set on the unit, the unit will activate a weak tone and switch the unit to the weather radio.

Hopefully you have seen the writeup I did on the reasoning for placement of the WAT in the coding sequence. If not, let me know and

I'll forward a copy. In the SAME environment, the WAT will continue to have a function if for no other reason than as an attention signal to the listener.

Subject: Re[2]: 1050HZ Warning Alarm Tone

The transmitter operates in the narrow band of FM (25 KHz channels). Modulation in this band is confined to +/- 5 KHz of the primary frequency leaving a 7.5 KHz guard on either side of the max. deviations. The audio level from the program console is supposed to deviate the transmitter at a minimum of 4.25 to a max. of 5.0.

We are finding that all over the country, many of our systems are not operating to that standard. We are not really sure how wide spread the problem is but we are taking steps to correct it. If you find the deviation below these stated levels, do not hesitate to call the NWS office and let them know.

Unlike the broadcast industry that uses some very high quality lines or RF Studio to Transmitter Links (STL), we use mostly voice grade telephone lines and the attenuation on these lines can vary. I will pass you comments and concerns on to the appropriate people there in the NWS.

Subject: Re[2]: 1050HZ Warning Alarm Tone

Please do let us know if you observe a problem with a system. We are in the final stages of developing a remote monitoring system but it is still a few months away so the eyes and ears of users such as yourself are appreciated.

Thanks for reading my post.
I need to know the value of R21 in RADIO SHACK MULTIMETER,
model 22-267. This is an Autoranging digital multimeter with three
banana jacks at the bottom labelled 10A, Common, V, ohm, ma, and diode.
R21 is part of the 10A circuit and mounted on the main board.
The color code can't be read now, cause of the discoloration
due to heat. It appears to be half watt wirewound, and last acted much
like a 'fusible resistor'. Any help would be greatly appreciated.
My name and call has been altered to protect my innosence.

Subject: 88Mh Coils needed

Anyone out there in Homebrew land have any of the famous 88 Mh repeater
coils? I am looking for 6 or 7 to send to a Ham in Japan so he can build
an inexpensive BP filter for RTTY. They aren't easily available there
apparently. I fyou have some you can spare, e-mail me.

Thanks, Russ Ellsworth,WA6CWV Boise,Idaho

I always thought that "homebrew" was a silly word to use in the
electronics field. Homebuilt would make a lot more sense and eliminate
this confusion with the homebrewing of beer and spirits, IMHO.

Subject: Chinese vs. American Tubes?

I have seen postings for 811A tubes of both American and Chinese
manufacture. Usually, the US tubes sell for two to three times the price
of the foreign tubes. I would suspect that the saying "You get what you
pay for" would apply, but I am curious if anyone has had any experience
with the Chinese tubes?

Thanks and 73's,

The "gotcha" on using a razor blade for the detector is it had to be a
"Blue Blade" (Gillette, if I recall.) These were coated (anodized?)
with a material that would behave as a rectifier. The connection could
be made via a wire wraped around a sharpened pencil lead. They probably
don't make these blades any longer :(

From: bry@mnsinc.com (Brian Carling AF4K/G3XLQ)
Subject: MINI-REVIEW: CPCW-5 xmtr

Someone please copy this mini-review to QRP-L

Here is a "First Impression" of the new CAKE PAN CW-5 transmitter
that arrived today.

It is a new TUBE product on the market for hams! What a great way for
all of those new NO CODE TECHS and other beginners to get their feet
wet with a REAL RADIO!

The radio can be bought assembled or as a kit. It comes with a really good manual and plenty of helpful instructions. Mine was already assembled and worked great right out of the box. I was on the air within 10 minutes.

This CW transmitting device uses a specially designed tranformer that is made just for this rig, plus a 6C4 - 6AQ5 tube line-up, plug-in coils and a PI-NET output. There is plenty of room on the chassis for your own mods or add-ons, and later this month they will begin offering an AM version of the rig, or a modification kit to add modulation to existing rigs.

I can see adding a semi-break-in circuit, maybe a relay for keying from my memory keyer etc, later. For tonight I just used the straight key.

This rig is destined to become a classic!
Once I figured out which tube went where and got the 6C4 and 6AQ5 tubes plugged in OK, I realized that the OTHER 7 pin tube socket is for the crystals to plug in! A novel approach. I had seen something like this done with FT-243 crystals in Octal tube sockets plenty of times.

I plugged it in and
connected an antenna (G5RV and MFJ-949D tuner) and plugged in the crystal for 3640 kHz that came with it. No one around so I tried a CQ. It only has ONE tuning control (plate variable) - the PI-NET has a fixed cap on the antenna side. No problem getting a full 5 watts out right away (according the notoriously inaccurate wattmeter used in tuners of this type) - but certainly in the ballpark of 5-6 watts out all of the time. The rig tunes nicely and has a good note.

Some RTTY signal is hogging the frequency and I get no replies to my CQs, so I plug in the 3700 kHz rock and move up the band.

SO at 0042 UTC I put out my first CQ on 3700 and got a reply from W8TMS in TROY, MI - DX!! AND he gave me RST 599! Not bad for a maiden viyage on the CPCW-5.
Later on I heard K3JO nearby calling CQ and gave 81 year-old Jules a call. He came right back and chatted with me for 35 enjoyable minutes. My report was RST 579 From Narberth, PA up near Philly using his homebrew 2-tube rig with a 6DQ6 final pumping 25 watts to an end-fed wire.

Later at 0135 UTC I tried a CQ again, and got a call from KR4LE. THe band was
getting noisier now, but Emery got me RST 599 in Richmond, VA

My last QSO of the evening came at 0211 UTC, again on 3700 kHz with KB1MJ up in Dedham, MA running a Heath HW-9 QRP rig.
Conditions were awful but Paul and I toughed it out!

I hope to work many of you soon with my delightful new glowbug here!
I will be QRV evenings on 3640 and 3700 kHz with the CPCW5 rig from

VINTAGE RADIO KIT COMPANY.

If you are interested - contact Carl, WB1EYE who supplies these kits
at:

427 N. Main Street
Sharon, MA 02067

or you can read more about it on my web pages at:

http://www.mnsinc.com/bry/hamfiles.htm

I have no financial interest in this company - just a happy user of
their product.

Anyone else using one - please contact me via e-mail at:

Subject: non-erotic, non-sexual, but possibly tantalizing linear pics

Already, I've gotten complaints from whiners regarding my linear picts.

Well, if political debates regarding "Little LEO's", whatever that means,
can occupy the NG, then you should be complaining to them, not me.

Also, I am very intereested in seeing others' homebrew projects captured
via QuickCams, etc.

If QST can begin with 20pp of pictures then we can assuredly do the same
with this NG. Also, I can put schematics onto JPEGS.

This is brand new territory with this NG, and I am already getting rave
reviews from some of the less timid QST authors.

Anyway, thanks for your time, Rob

I vaguely remember that the blue finish involves heating with a coating
of carbon powder on the surface. Something similar is used with gun
barrels, I think. The iron carbide layer must act as a semiconductor.

of the HV transformer. The secondary of the small transformer is
rectified, filtered, and used to power the DC coil of the step-start relay.

The step point can be contolled by placing resistance in series with the
relay's coil.

Subject: Soft-start circuits

Well, for what it's worth....

Back a couple months ago, we had the mobile TV truck over at our Gym for
a basketball game. We plugged into a service outlet on the outside of the
building. We ran camera cables inside, intercom cables, video for the
announcers booth, audio back down from the announcers booth, you get the
idea.... Well the monitor that the announcers had was a 117VAC grounded
plug. We plugged the monitor into a outlet in the announcers booth instead
of running AC all the way up to it from the truck. Well, as it turns out,
and no one knew this, the whole ground system inside of the gym was not
bonded to neutral or the ground rods at the service entrance. A transformer
shorted in one of the lights inside of the gym and was putting 600VAC on the
whole ground system. The outlets we were plugged into on the outside of gym
were grounded. When the monitor was plugged in, a ground fault breaker
opened. The engineer who was working the truck that night didn't know what
was happening and why the ground fault breakers in the truck kept opening.
He unhooked the video and audio lines to the announcers booth. Presto, no
breaker opening up. He reached over and started to grab the video line with
one hand while his other hand was pressed against a tape machine (case grounded
of course), he was knocked out backwards of the truck, blacked out when
his head hit the ground. He had holes in 3 fingers that touched the video
connector. And if all than wasn't enough, he had a heart pacemaker.
He lived and is doing fine, fingers healed, no problems with his pacemaker.
We now call him LUCKY.

Is there a need for the ground separate from the neutral? Well the system
that was supposed to prevent this, was actually worse than if we had no
ground at all. This was a electrical problem that should have been caught
when the building was constructed. Times past we plugged into the outlets
and had no problems, why, because the transformer was not shorted to
ground. It's amazing someone didn't get killed. The ground and neutral
have to be bonded together at the service feed point for the ground safety
system to work, otherwise you are better off without it. People who work

in the electronics industry naturally 'assume' that ground is ground.
That's a deadly assumption.

My $0.02 worth as well.

Subject: Want Camcorder for ATV use - cheap

Thanks for reading this. I'm looking for a color video camera that I
can use for ATV but don't have much cash so a broken camcorder will do
just fine if the camera part still works and I can get video out.
Let me know what you have and how much you want for it.
$60 is my limit for a broken camcorder.

'RF VOX' controlled TR switching always strikes me as slightly Mickey
Mouse.

Unless you are using very low power levels, you always wind up with
undesirable side effects such as hot switching the relay contacts and
pumping RF into the preamp output, as indicated by Paul.

It has the potential to eventually fry the relay contacts and/or cause
preamp, RF final failure.

My suggestion is to do it properly, run a control wire up to the
preamp and use properly timed switching to avoid any of the above. The
ARRL handbook has a TR switch sequencer in it if memory serves me.

>
> 73 & good luck de Laurens

He already has the vfo, thats the "oatmeal box" or "toilett paper roll"
inductor with a variable cap. The crystal he's referencing is the one
used to detect the audio from the AM signal not one used in the vfo.

You could build a variable cap, but Im pretty sure the default meathod
would be to build an inductor around a tube, about 160 turns of #22, 24,
26 wire around a toilett paper roll will get you in the ball park for
use with a 365 pf cap. You can use a fixed value cap and then build a
device to allow you to slide along the inductor. Glue the coil to the
form with dope and when dry use very light sandpaper to remove the
insulation in a straight line across the coil, your frequency will
change depending on where you tap the coil.

You will definatly need a set of old WW2 high impeadence phones or a
cyrstal earphone, there is not enough energy to drive 8ohm headsets or
speakers.

To keep your spirits high though, you may want to use a 365pf tuning cap
from an old AM radio and use a diode instead of the cat whisker
arrangement. Once you get that working you can experiment with different
detectors and tuning meathods. I just finished one for my bosses son

using the above. They are still fun to build.

3306. 2SC2221 ---> NTE322??

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-03-23 00:00:00 UTC
From: jeffreyh@Hawaii.Edu
Message-ID: <5h2afl$37g@news.Hawaii.Edu>
Source record: 95650

Hi folks - I melted the 2SC2221 transistor in the final amp of my
Tempo S1 HT. Honolulu Electronics says that a replacement for the
2221 is an ECG322, and a replacement for that is an NTE322 (which
is what they sold me).

Two things bother me:
1. The 2SC2221's case was similar to a TO-39 (round, metal); the
case was soldered to the circuit board ground (for heat dissipation
I suppose). The NTE322's case is similar to a TO-220 and is plastic.
Should the NTE322's metal stub be soldered to ground?
(i.e., are the 2221 and 322 electrically identical? I'd hate
to ground the case if its not meant to be.)

2. The small amount of data that came on the 322 package says:
"NPN - Si, RF Pwr Amp, CB, Po 3.5W Min, 27 MHz"

This 2m HT (with the original 2SC2221 PA) was rated at 1.5W output.
Can I exppect the NTE322 "CB PA" to have a similar output at 2m?

Thanks in advance!

>and against wiring standards.

My Heath transmitters are wired that way. If a filament was above
ground potential couldn't that adversely effect the operation of the
tube? Electrons boiled off the cathode might flow towards the
filament instead of the plate.

From: jspatric@mailhost.ecn.uoknor.edu
Message-ID: <5h20c1$6tp$1@independence.ecn.ou.edu>
Source record: 95768

I'm designing a preamp (with RF sensing) for 10m, 2m, 70cm, and whatever other bands I need one for. I have designed one for each with standard N-channel MOSFETs. Now, I see that all the preamps sold advertise GaAs (Gallium Arsenide) FETs. I've looked in my Digikey, Mouser, etc. catalogs, but cannot find a GaAsFET. Where can I buy one? if you can help me out, I'd really appreciate it. If everything goes well, I may try to publish the designs in some Ham-related magazine. The way I've designed the ones so far, to choose which band you want, you just change the values of parts in the design. All the preamps have the same template (sorta).

Thanks,
John

Hi John --

Why would you want use an expensive GaAsFET in a 10 meter
preamp? There are plenty of good low-noise FETs or bipolar
devices that will do just fine up to and including two-meters.

In an amplifier that uses 240v single-primary transformers, Wes, neutral is not connected in any way to the transformer windings. Thus, no current flows through the neutral wire whether one or two stepstart resistors are used. The safety ground/neutral wire is connected to the amplifier chassis whether one or two stepstart resistors are used. What safety issues?

> THE NEUTRAL IS TIED TO EARTH AT THE SERVICE ENTRANCE.....

True.

After that, it is
> treated as a current carrying conductor.

NOT in the case described above. Please explain how the neutral could carry fault current from the HV supply.

If this is not of interest to you, please accept my apologies for intruding on your newsgroup and ignore this. If this is a pictures newsgroup I will follow this post up with some tasty pics. I hate spammers as much as the next guy, but we're talking about some very easy money to be made !! If you are still interested (and YOU SHOULD BE)......

-!!!-PLEASE READ THIS VERY IMPORTANT NOTICE- NOW!!!
!!! MAKE MONEY-LEGAL AND EASY WITH YOUR VERY OWN MAILING LIST BUSINESS!!!
THIS IS THE FAIREST, MOST HONEST WAY I KNOW OF TO SHARE THE WEALTH!!

Hello! Would you like to make thousands of dollars,quickly, legally, with NO CATCH? Then keep reading.... Please take a few minutes to read this article, and it just may just change your life. I SWEAR I'M NOT LYING TO YOU, ANDTHIS IS NOT A SCAM! If you're interested, please, keep reading. If you're not, then, again, I apologize for wasting your time.

The following concept of making money with your computer essentially began in the US and has now spread throughout the Western World. It is perhaps unique inasmuch as there's no risk - people from all over the world are currently participating and those that follow the initial concept are earning large amounts of cash.
Read the following carefully and you too could be joining the many thousands of Internet users who are currently earning quite reasonable sums of money with a few hours work using their computers via the Internet!
****
This posting has been appearing for quite some time and has now literally got thousands of people actively involved. No doubt like me, you may have seen it before and become a little confused by the way it's been explained. However, I personally have never believed in a so called "Free lunch" and have always worked hard to support my family. But this idea is so simple involving only a modest $5.00 investment that I simply had to try it. At first, it took me quite a while to figure it out - my first impressions led me to believe that there must be some catch to it. But this isn't so, you only have to look at the various postings to realise this; the thousands of postings that are made all carry different names and addresses. So with so many people involved I became convinced that with this particular program I too could benefit. Although many of the postings have been modified the

basic principal remains the same, in my opinion the only problem has been the way the initial concept has been repeatedly changed.
With this in mind I have set out to explain what I consider to be a clearer version, in the hope there is no doubt in people's minds that it's fully understood. Because believe me, this system does work!
****
Essential Information to Assist Your Success!!

These articles have been modified over and over again, and embody over exaggerated claims of vast earnings. While this cannot be disputed it is essential in order to receive the attention of those who read it to post an article that gives out the right signals to the recipient. I believe this article does just that, it's not full of unnecessary $$$ signs, neither does it contain ridiculous claims which only puts people off. If you want to get started right away, simply amend the address section by removing the top location and place your own name and address at the bottom.
****
In general, these postings lead you to believe you can make $50,000 within a month, which I think is a little over the top.
But now after only a few day's of my initial involvement, I'm beginning to get a reasonable and realistic return with a further understanding of just how big this concept is. The money is coming in from all over the world, and sure comes in useful but what's more important is the fact I have proved this to be a totally workable and legitimate system, involving no risk and no major cash outlay.
My other concern was the legal aspect, so I checked this through and was told that providing I mail one dollar to the person I am asking to put me on their mailing list, I am in fact paying for a service. And that service consists of using the Internet to advertise a business.
So what is this business? Well this business is to do with assembling a mailing list of people who are interested in working from home using their computers to generate an income.
****
Ok...if your interested there are three basic steps: All of which are pretty simple. Think positive, after all, the people below became involved just like you!

Let me tell you how AND WHY this works .. also, MAKE SURE YOU PRINT A COPY OF THIS ARTICLE NOW, so you can get the information off it as you need it.

STEP 1:
Get 5 seperate pieces of paper and write the following on each piece of paper "PLEASE PUT ME ON YOUR MAILING LIST." (In this way you are not just sending a dollar bill to someone, you are paying for a legitimate service.) Fold a $1 bill inside each piece of paper with your name and address on it, and mail these 5 letters to the following 5 addresses:

1- SRO Services
PO Box 909
Puunene, HI 96784
USA

2- Aumakua Enterprises
PO Box 277-316
Kihei, HI 96753
USA

3- Ross McCrindle
2-28 Cambridge St. S.,
Lindsay,Ontario
K9V 3B6
Canada

4- Sean Ringle
PO Box 1
Lanesville, IN 47136
USA

5- Ron Campbell
106-1309 West 14th Avenue
Vancouver BC V6H 1R2
Canada

STEP 2:
Now take the #1 name off of the list that you see below, move the other 4 names up. (5 becomes 4, etc.) and add your own name as number 5 on the list.

STEP 3:
Change anything you wish to, but try keep this article as close to original as possible. Now, Post your amended article to at least 200 newsgroups. (there are around 19,000 groups). All you NEED is 200, but remember, the MORE YOU POST , THE MORE MONEY YOU MAKE!!!

You are now in the mailing list business, and should start seeing returns within a week or two. Of course, the more newsgroups you post to, the greater your return will be. If you wish to remain anonymous, you may use a pseudonym, but make sure address is correct.

LEGAL ???

People have thoroughly discussed whether this is really legal. You are using the Internet to advertise your business. What is that business? You are assembling a mailing list of people who are interested in home based computer and online businesses and methods of generating income at home.
REMEMBER - people send you small fee to be added to your list. It is legal. What will you do with your list of thousands of names? That's up to you.

HERE IS WHY THE SYSTEM WORKS:

The internet is growing at a tremendous rate - it doubles in size every 4 months. Think about it. You see those "Make Money Fast" posts more and more. All that growth means potentially big profits for everyone who participates.

Of every 200 posts you make, you should receive roughly 5 responses. That probably doesn't seem like much. You make $5.00 for every 200 posts with your name at #5.

Each person who sent you $1.00 now also makes 200 additional postings with your name at #4. i.e. 1000 postings. On average, 50 people will send you $1.00 with your name at #4. That's $50.00

Your 50 new agents make 200 postings each with your name at #3 or 10,000 postings. Average return 500 people=$500.00. They make 200 postings each with your name at #2=100,000 postings=5000 returns at $1.00 each=$5,000.

Finally, 5,000 people make 200 postings with your name at #1 and you get a return of $50,000 before your name drops off the list. AND THAT'S IF EVERYONE DOWN THE LINE MAKES ONLY 200 POSTINGS! Potential income in one cycle = $50,000.

REMEMBER THIS ---- thousands of people all over the world are joining the internet every day and reading these articles every day just like you are now. So can you afford $5 dollars and see if it really works??? I think so.....

Lets review why you should do this. THE ONLY COST IS $5.00, 5 STAMPS, AND 5 ENVELOPES. Anyone can afford $5.00 for such an effortless investment with such SPECTACULAR RETURNS.

There are millions of internet users, and millions of new net surfers every month. REMEMBER - read the instructions carefully, and play fairly. THAT'S the only way this will work. Get a printout so you can refer back to this article easily.

Keep a list of everyone that sends you money, keep good books, pay your taxes, and always keep an eye on the postings to make sure everyone is playing fairly. You know where your name should be.

If you're really not sure or still think this can't be for real, then don't do it. But please print this article and pass it along to someone you know who really needs the bucks, and see what happens.

REMEMBER - HONESTY IS THE BEST POLICY. WHAT IS $5.00 TO YOU? YOU DON'T NEED TO CHEAT THIS IDEA TO MAKE MONEY!!! This is the easiest way that you can make a buck. Think how excited you'll be to open up your mailbox day after day! Will it be $50.00 or $5,000.00?? Start making your plans, because it can happen to you.

DON'T PASS UP THIS ONCE IN A LIFETIME OPPORTUNITY

The problem is that when the 240vac from the HV transformer primary winding
is rectified and filtered, it produces an unwieldy 300vdc. Since 24vdc
relays are fairly common, when I specify the windings for a Peter Dahl
custom made transformer, I include a 15vac@1a winding to power the
step-start relay.

HV-RFC arcing is most commonly caused by a self-resonance in the choke being too close to an operating frequency. This problem can be avoided by checking the choke with a dipmeter after it is installed--before 'firing up'. If you find a self-resonance within 5% of an operating frequency, remove turns as needed---unless you are into fireworks.

The only amplifiers I know of that have a HV-RFC VHF-resonance problem is the Henry 2K4/3kA series that use a 29uH HV-RFC, which Henry says has 50uH.

This may be an old question, so my apologies upfront.....

Does anyone have any recommendations for software for creating schematics and wiring diagrams? I have tried a couple of low-end programs and found them too labor intensive and not really suitable.

I'd appreciate anyone's suggestions, recommendations, and/or ideas.

Thanks in advance.

...snip...

So it seems, Rob. There is normally no connection between the
neutral/chassis wire and any part of the step-start circuit, so it matters
not whether one or two step-start resistors are used.

EDITORIAL: It seems to me that it might be a good idea to take a look at a
schematic diagram before looking for the 'Send' button.

Since posting the above, I have received 37 replies telling me it
can't be done.

To most of those I did not replly.

Several said it caint be done, but if it looks interesting, send it to
me, and I MAY get interested.

to all but one of those, I said "the world is full of people who
got no idea what is going on, but who know why it won't work.

I wish to call to everyone's attention that Lee DeForest was
sued by the then scientific authorities to keep him from putting a
triode on the market ! ! !

I believe everyone knows that almost every home in the USA
and most other industrial countries has at least one LARGE triode or
bigger tube in their TV.

Semmelweiss, and Pasteur, and God alone knows how many others have
seen this from the sharp end, and repeatedly proven that if you don't
know, you don't know. BUT the "wisdoms" of theland, still can tell us

why whatever it is don't work, even though they've never seen one.

Ain't it a wonderful world?

To top it off, I recently read a book by Georgetta Heyer (The
definitive historian in several places) who wrote several light
Regency novels, and in one of them the hero says to a girl
"There is no sense to tell me I can't do what I HAVE done."

I say the same.

Ciao, people.

> 73 de Laurens

The tinning handles RF slightly, but has offsetting problems when the
surface begins to passivate.

Generally, the only reason I use tinned wire for a big RF coil is to
make it easier to solder a tap in place when the coil is already
installed. Scraping can be a **** then.

For real fine tuning of a coil of that sort, you often want it in
circuit, surrounded by all its chums before final placement of taps.

Hope this helps.

Two programs, I know of, are Electronics Workbench and CircuitMaker.

These programs let you draw AND debug (both analog and digital) circuits on your computer. Both also cost about $300 each. These may be more than you are really looking for.

A good reference for these and (drawing only) software would be Electronics Now magazine "www.gernsback.com" who, recently, did a comparison of several drawing and simulation software packages.

Hope this helps.

3329. Does this sound good???

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-03-23 00:00:00 UTC
From: Thor Harald Johansen <thorhajo@arcticnet.no>
Message-ID: <3335A5C9.38C4@arcticnet.no>
Source record: 95788

This is a WEB-page about the NorCal 40A CW-Transceiver. Will someone reply to me, and tell me if this is a good choice for a transceiver?

----------CUT----------
The revision B NorCal 40A is a third-generation 40-meter QRP transceiver kit, designed by Wayne Burdick,
N6KR. The rig covers any 40KHz portion of the CW band, with a very stable VFO operating in the 2MHz range.
The receiver is a superhet with crystal filter, AGC, and RIT. The frequency coverage can be increased up to
150kHz with one capacitor change. Since varactor tuning is used, a 10-turn potentiometer can be substituted for
the supplied 1-turn unit if better tuning resolution is desired. (If you make this modification, we suggest using the
KC1 Keyer/Frequency Counter for keeping track of your operating frequency.)

The first batch of NorCal 40A's had significantly better performance than the original NorCal 40, having more
AGC range, a more stable VFO pot, and a more sensitive receiver that would drive a speaker directly. The
Wilderness kit (revision B), besides having a painted and screened enclosure, has a number of additional
refinements. These include improved receiver image rejection, better-sounding AGC and QSK, and a bit more
power output (around 3 watts with a 14V supply).

Receive-mode current drain is VERY low--about 15mA--leading to long battery life for portable operation. The
transmitter puts out 1.8 to 3 watts, depending on supply voltage, and has full QSK.

Physically, the rig is very small (2.25"H x 4.5"W x 4.5"D), about one-half the volume of an OHR Explorer. One
double-sided, screened and plated through PC board is used. There is NO chassis wiring: all controls and
connectors and even the case parts themselves mount directly to the board, resulting in an uncluttered interior.
The custom .060 case is quite rugged, and is designed to allow the top and bottom to be removed easily for
alignment or test. Long-life plastic latches are provided on the top so no screwdriver is needed to access internal
controls.

The '40A has plenty of empty front- and rear-panel and interior space for your modifications. Wilderness Radio

encourages you to customize the '40A, and will continue to provide support, even if you put it on 80 meters or some other band! The rig comes with a professionally-written, 30+ page assembly and operating manual.

What others say about the Norcal 40A

"Most of all, however, it was the quality of the kit--board, silk-screening, and case--and the excellent manual, that really made this a great FIRST kit for me. Wayne and the NORCAL gang really deserve an enormous hand for their efforts...kit building has been something I always wanted to get my feet wet in, and this was a fine, encouraging introduction." -- Matt, KN6CR

"I continue to be amazed at the receiver...I often put a separate 40m antenna on the NorCal and on my Yaesu 990, then stick one earphone from each rig on my head. The NorCal is much, much quieter than the 990. Weak signals are far easier to copy on the NorCal. I've told friends of this phenomenon, and they just don't believe me. I think you have to hear it to believe it." -- Bruce, AA6KX

NorCal 40A compared to similar kits:

-By far the cleanest construction of any low-cost kit.

-Much lower receive-mode current drain than the OHR Explorer and most other kits.

-Rock-stable down to a battery voltage of 9.5V.

-Compared to the SWL NE40-40, you'll get much higher performance, plus all the controls and connectors, no chassis wiring, and a custom, painted/screened enclosure

-Proven highly stable in the field due to its ultra-low frequency VFO

-KC1 Keyer/Frequency counter is tailored to the '40A, providing much more functionality than Curtis 8044-based keyers

NorCal 40A Pricing

The new Wilderness NorCal 40A is $129 plus shipping ($5 U.S., $10 Canada/Mexico, $15 DX).

HELP! COSSOR SCOPE /EHT transformer RQd

BY any chance has anyone ex-cossors/harlow etc
got in their junk box a COSSOR CDU120 little
EHT transformer-4 inches square,5 -pins primary
and 2 pins secondary(1kv and 2kv),ferrite core?

or has anyone got an old CDU 110,120,150 for
spares/repair in their junk shack?
I believe I saw one at Cambridge ham rally
end Febuary-but mine was ok then!

If not does anyone know calendar dates/locations
of Sunday Ham Rallies this year?

You can try it, but it won't work. You need a germanium diode, not
silicon. Try a 1N34A.

Oven Controlled Crystal Oscillators OCXOs at 16.384 MHz.
These PCB mounting hermetic oscillators are 77X51X32mm high they divide by 2 to the power 14 to give 1 kHz to function as the reference for frequency synthesisers as used in instruments, radio, cellular, TV Transmitters..
Oscillators are stable to a few parts in ten to the ten over 1 second and to parts in ten to the nine over -40+70C. Supplied with calibration data so can be used to check counters etc to +-0.2ppm.
SSB noise plots available showing -125dbc@+-10 hz -155dbc floor
12 V supply 600mA on warm up
200mA when running@23C
Warm up time 6minutes approx.
Built in 8V reference so that fine frequency adjustment can be carried out with external potentiometer.
Electrical control of frequency (typical) +0.12ppm/Volt
These units are latest technology incorporating SC cut low ageing crystals typically < 0.1 part in 1 million / year.
Output 1.5Vpp 50ohms source resistance.
CALIBRATION
Every unit supplied with Voltage to apply to freq control pin to set to nominal frequency +-0.1ppm.............

> clearly points out in his post.
>
> N7WS

Not so, if you follow all these circuits that tie bypass capacitors
and MOV surge suppressors from the hot 230 and neutral back to
chassis ground. If any of these devices conducts surges and
spikes to ground, then ground is carrying these.

It seems to me, that these surge suppressors could actually be
increasing power line noise EMI, which I was trying to eliminate.
So I am inclinded to just place these devices across the 230 and
to neutral.

Please comment. I am about to put in a bunch of these in my
rewiring and EMI compain.

73, Don, N6MCE

PS. I was using a slow start circuit, put the bounce in
my relay was blowing fuses. So I put a diode in series with
the 120 volt relay coil. Then the relay went up in smoke and flames.
Luckily I was there and blew it out. So I now switch on the whole load.
So far, it works.

Why won't it work, if you have enough signal strength?

The Si diode only takes about 2x the voltage to conduct as the Ge diode...

Am I missing something?

(Not that 1N34A's are that hard to get)

Source record: 95657

GL Has given a wiring diagram for example.

1995 Handbook page 123.31 ; The 1500 watt amp using 3-500z.

Where is the problem? I think this is one design that conforms to the code. They have kept the ground separte from the neutral. The chassis is connected to the ground. They have used the neutral for loads, using the ground for saftey.

Is it the B+ return raised above ground potential by the metering resistor? Isn't the resistor there so the meter does not need an insultion for the 4KV B+ supply? Not many 1 amp meters are rated for 4KV ? Is there a problem with this? Have I missed something?

The post about transient supressors, the commercial units I have seen by-pass the (240vac) Hot(line) to Hot(lline); Hot(Lines) to neutral; then neutral to ground: This is not to say that is right just what I have seen.

UHF Power Amplifier Modules

The MITSUBISHI M67729H2 has been developed and produced in large
quantities
for UHF cellular telephone applications.

Technical Data:
Output Power = 20 W
Gain = 21 dB
Harmonics = -40 db
Spurious Outputs = -70 dB
50 Ohm in/out

This module is also excellent suited for class C Amateur Radio PA's in the
70 cm-Band.
The low output of a UHF handheld may be amplified to about 20 W output! The
use of these modules is the easiest way to build a PA. There are various
discriptions in the ham literature.

I am now able to offer you this excellent module with a more than 10 dB!
price
reduction:

1 ea for DM 35,--
10 ea for DM 300,--

plus postage with C.O.D. charge.

>Could this really be something, unstabilized screen supply?

That is the worse imaginable way to get sceen voltage.

It is a very high IMD circuit.

The loading on the exciter varies with drive and screen current, since
the rectifiers load input RF on peaks ONLY.

I measured several PA's built this way, and the IMD was worse than
placing them in simple grounded grid.

That is probably why the circuit never became accepted in popular
usage.

Stick with your regular circuit, it works much better.

Ham-Homebrew Digest Mon, 24 Mar 97 Volume 97 : Issue 210

Today's Topics:
900 mhz amateur operation
C&K DT-3 10 Ghz Gunn DATASHEET
Drawing Software
GaAsFETs: Where to buy them?
Home made crystal(?) radio (3 msgs)
PHOENIX-SX Need Help !!!
Radio Shack Multimeter
Scanner -> Freq. Synthe?
Schematics and plans online
Screen supply
Soft-start circuits
Texas TIC108?????
WTB Millen Band Switch

Two programs, I know of, are Electronics Workbench and CircuitMaker.

These programs let you draw AND debug (both analog and digital) circuits
on your computer. Both also cost about $300 each. These may be more than
you are really looking for.

A good reference for these and (drawing only) software would be
Electronics Now magazine "www.gernsback.com" who, recently, did a
comparison of several drawing and simulation software packages.

Hope this helps.

Why won't it work, if you have enough signal strength?

The Si diode only takes about 2x the voltage to conduct as the Ge diode...

Am I missing something?

(Not that 1N34A's are that hard to get)

> 73 & good luck de Laurens

He already has the vfo, thats the "oatmeal box" or "toilett paper roll" inductor with a variable cap. The crystal he's referencing is the one used to detect the audio from the AM signal not one used in the vfo.

You could build a variable cap, but Im pretty sure the default meathod would be to build an inductor around a tube, about 160 turns of #22, 24, 26 wire around a toilett paper roll will get you in the ball park for use with a 365 pf cap. You can use a fixed value cap and then build a device to allow you to slide along the inductor. Glue the coil to the form with dope and when dry use very light sandpaper to remove the insulation in a straight line across the coil, your frequency will change depending on where you tap the coil.

You will definatly need a set of old WW2 high impeadence phones or a cyrstal earphone, there is not enough energy to drive 8ohm headsets or speakers.

To keep your spirits high though, you may want to use a 365pf tuning cap from an old AM radio and use a diode instead of the cat whisker arrangement. Once you get that working you can experiment with different detectors and tuning meathods. I just finished one for my bosses son using the above. They are still fun to build.

Subject: Radio Shack Multimeter

Thanks for reading my post.
I need to know the value of R21 in RADIO SHACK MULTIMETER,
model 22-267. This is an Autoranging digital multimeter with three
banana jacks at the bottom labelled 10A, Common, V, ohm, ma, and diode.
R21 is part of the 10A circuit and mounted on the main board.
The color code can't be read now, cause of the discoloration
due to heat. It appears to be half watt wirewound, and last acted much
like a 'fusible resistor'. Any help would be greatly appreciated.
My name and call has been altered to protect my innosence.

Subject: Screen supply

Hello everybody!

I've built a amplifier with a pair of 4x500 tubes for several years ago,
and it is grid driven. A good friend of mine told me how to fix the
screen supply voltage in a way i've never heard before, now i use a
seperate stab supply for the screen. Thing is that i did not quite
understand all of it, he promised to send me a schematic digram over the
circuit, but he has probably forgotten it.
He said that you rectify part of the rf double or triple and fed it to
the screen grid. And the big advantage was that the amplifier became much
easier to drive.
Could this really be something, unstabilized screen supply?
Any thing on the subject will be greatly appreciated whether it come to
ng or my e-mail adr.

Thank's in advance!

HV-RFC arcing is most commonly caused by a self-resonance in the choke
being too close to an operating frequency. This problem can be avoided by
checking the choke with a dipmeter after it is installed--before 'firing
up'. If you find a self-resonance within 5% of an operating frequency,
remove turns as needed---unless you are into fireworks.

The only amplifiers I know of that have a HV-RFC VHF-resonance problem is
the Henry 2K4/3kA series that use a 29uH HV-RFC, which Henry says has 50uH.

Correct: in this case, the former owner of this Alpha 77D amplifier tried
to operate it on 24 mhz to ill effect. The original plate choke in this
unit is a B&W number 800 with 6 turns removed. Judging from the evidence,
it would appear that the 24 mhz self-resonance broke the winding, thereby
unraveling the coil, thereby shorting 4000 VDC to ground in several places
as it unwound. "Fireworks" might be too restrained as a descriptive term.

HE Johnson - - W4ZCB wrote:

3351. WANTED: plug-in coil forms and sockets

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-03-24 00:00:00 UTC
From: k5dh@dlep1.itg.ti.com
Message-ID: <5h6bli$b32@sf18.dseg.ti.com>
Source record: 95664
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.boatanchors

I need at least two each of the old plug-in coil forms and sockets for a CW transmitter project I'm working on (a 6V6 oscillator driving an 807 PA). Either 4-pin or 5-pin types would be fine, about 1-1/4" in diameter or close to that.

I could also use a couple of Millen ceramic plug-bars and jack-bars for my parts stock (future projects, y'know?).

ALSO... I need some B & W 3011 and 3015 coils (unused only, please) for transmitter projects.

73 de K5DH! :)

88 mH toroids are probably very difficult to obtain, now. He could get
some pot cores and wind his own.

Subject: Drawing Software

This may be an old question, so my apologies upfront.....

Does anyone have any recommendations for software for creating
schematics and wiring diagrams? I have tried a couple of low-end
programs and found them too labor intensive and not really suitable.

I'd appreciate anyone's suggestions, recommendations, and/or ideas.

Thanks in advance.

OKI have a Speech Pitch Controller chip, the MSM6322GSK, that should do
what you want. It costs #10.20 (UK) from Maplin, and the circuit is in
their current catalogue. You can shift the pitch of input speech in 17
steps either one octave up or one octave down. Maplin is on 01702
554000.

You can try it, but it won't work. You need a germanium diode, not
silicon. Try a 1N34A.

I vaguely remember that the blue finish involves heating with a coating
of carbon powder on the surface. Something similar is used with gun
barrels, I think. The iron carbide layer must act as a semiconductor.

The problem is that when the 240vac from the HV transformer primary winding
is rectified and filtered, it produces an unwieldy 300vdc. Since 24vdc
relays are fairly common, when I specify the windings for a Peter Dahl
custom made transformer, I include a 15vac@1a winding to power the
step-start relay.

3353. ScoutElmer Award for you!

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-03-24 00:00:00 UTC
From: myriad1@ix.netcom
Message-ID: <myriad1-ya02348000240397100017000 1@nntp.ix.netcom.com>
Source record: 95666
Cross-posted to: rec.radio.amateur.digital.misc,rec.radio.amateur.dx,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc

YOU DON'T NEED TO BE A SCOUT OR LEADER TO EARN THE ScoutElmer AWARD!!!
ScoutElmer Award for helping Scouts become ham ops

WHO QUALIFIES FOR THE AWARD?
1. Licensed ham op (any level)
2. Scout or Adult Leader (past or present) or...
3. Any ham that know someone (Scout or leader) currently active in a Scout unit.

WHAT IS REQUIRED FOR THE AWARD?
1. Agree to respond to Scouts via email with their questions about ham radio in your local area, for 1 month.

HOW DO I SIGN-UP FOR THE AWARD?
Email to the address below and fill in the blanks.... that's it!
1. Name & Ham Call Sign:

2. Email address:

3. Locations: (ie London, UK; Los Angeles, CA, USA; etc)

4. What do you want to do: (email only; email & phone; email, phone & ham class)

5. Your Scout affiliation & position (enter past affiliation and date if applies):
(If no current or past affiliation) Your Scout or Scout leader sponsor:

6. Optional comments for your ScoutElmer listing: (ie. ARC Club listing, Explorer post, Troop etc.)

WHAT DO I GET?
ScoutElmer Award recipients will receive special award logo graphic you can add to your website. You also get a certificate (suitable for framing).
Lastly the satisfaction that you helped promote amateur radio in Scouting.

If you've already applied for the award, sorry for the email. You should receive confirmation in the next few days.
YIS

ASM Troop 319 & Webmaster Advisor
myriad1@ix.netcom.com
http://www.ocbsa.org/troop319/ham.htm

ScoutRadio WWW is a "good turn project" of Troop 319, Huntington Beach, California USA.

There are over 250,000 (500,000 worldwide) hams who are or have been envolved in the Scouting movement, helping their communities in times of natural disasters, emergencies and humanitarian aid. We hope you or your ARC can help local Scouts get into ham radio and keep the amateur radio service strong.

You'll probably give up trying to get your 900Mhz unit to talk farther,
it's down to the design.
I sell Long Range Cordless Phones and to get decent range at 900Mhz you
would have to run to a non-approved unit. Some of the Panasonics claim
several Km, but even with the optional antenna for the base thtill ..P.
I don't know what country you are in but you may wish to check out the
different frequencies allowed and consider trying somerthing else.
I've put a marine cellular 9db antenna on a Rabbit 900Mhz digital phone,
even with seriously expensive coax and it;'s still C..P!
I could bancrupt you and sell you a Senao unit out of Taiwan to give you
50Km+....

Look again. Tansformers and other 120 v devices return to the chassis.
That is against code. If the ground lead would ever fail, the chassis
would be at 120 volts!

All line operated devices need to return only to the power line
neutral, and not be connected to the chassis by any means.

Only the safety ground should be connected to the chassis.

Read the text, they specifically tell you the chassis MUST be
insulated from the cabinet.

Please tell me HOW to build a shielded RF amplifier, and insulate the
chassis from the cabinet.

> Is it the B+ return raised above ground potential by the metering
>resistor? Isn't the resistor there so the meter does not need an
>insultion for the 4KV B+ supply? Not many 1 amp meters are rated for
>4KV ? Is there a problem with this? Have I missed something?

Yes, if there is a fault the negative rail will fly up to full high
voltage. Negative rails should be clamped with diodes, and other
compinents that fail shorted. Not with resistors that fail open during
faults.

> The post about transient supressors, the commercial units I have seen
>by-pass the (240vac) Hot(line) to Hot(lline); Hot(Lines) to neutral;
>then neutral to ground: This is not to say that is right just what I
>have seen.

But the neutral is not grounded to the chassis or safety ground, only
a safety ground is tied to the chassis.

Tom:

Ok. I agree on the clamping of the resistor. I can see how it will take
time to open the fuses in the primary of the step start circuit. During that
time the B- rail will go twords B+ with respect to the chassis ground.

Hi All,

I'm looking for a solid state Grid Dip Meter (preferably the Millen
Solid State version). Delivery is to Israel.
Can anyone help?

regards,
techno

(P.S: please email me directly in addition to posting here, so no
responses are missed. Thanks!)

He (designer) has put the chassis off from ground. If this chassis is in another enclosure (cabinet) and the cabinet is ground has this violated the code? How many analog/digital systems are around that have two or three levels of ground? Once inside the enclosure which is "grounded" can you run another rail?

You must have either one of the poorer designs, or a defective unit.

I have two Uniden 900 MHz units: the EXP-901 (? model from memory) and the
EXP-9100 Spread Spectrum version. Both have a range of 2500+ feet with the
base in my office inside a brick home on the first floor. At work, I can
roam a 5 story brick/steel/concrete building with very few dead spots,
including none in the computer room.

You can buy these phones for $125-150 at discount stores, maybe even less.
I had a GE, and took it back because it was worse than my Uniden 46 MHz
model.... YMMV

(all views are my own, I don't have any interest in any commercial co., etc..)

I've heard that silicon carbide can be used. The forward voltage drop
is a bit on the high side for a crystal receiver, but I remember seeing a
circuit using a "D" cell and a 1 meg pot to forward bias the silicon carbide
almost to the point of conduction. A very tiny radio signal could push it over
the edge.

Another interesting detector I have read about is called a "ticker".
Basicially it amounts to a small brass pulley on the shaft of a little motor.
One pole is a brass contact which slides on the face of the pully. The
other contact is composed of a piece of music wire or other springy wire,
which is laid in the groove of the rotating pulley, and kind of drags there. I
here tell that it is essentially useless for am, but that you can actually
hear cw morse code type stuff with it. (This is circa 1915-1920)

Still another involved a flat razor blade and a pencil lead. The blades are
(or at least were!) plated or or sputtered with a thin layer of something to
discourage corrosion. This in combination with a small piece of graphite
apparently creates a nonlinear junction - a diode if you will. I have my
doubts about the sensitivity of this device, but I suppose you could forward
bias it like the carbide and get more sensitivity out of it.

I would advise to NOT use these chargers, Sam. The current capability of both units far exceed the maximum safe charging current for the NiCads in the 202's battery pack. The packs get quite warm using the standard 200 mA charger; imagine what a 1000 mA charger will do. If I have the time I usually charge my 202 with a 50 mA supply: Much kinder to the NiCads.

I remember reading about making a detector using a penny (or other piece of metal) and touching a thin wire to it (the cat wisker). It appears that any corrosion on the surface will give the non-linear contact. I've never tried it, but I remember reading about it - maybe 20 years ago. Good luck.

Source record: 95679

Thanks for reading this message.

I am in the process of nutting out a 2m xtal controlled TX strip to be used for packet. FM is obtained from a varicap diode across the xtal.

My question is: how much pre-emphasis (dB/octave) should I apply, and at what frequency should it start? My books talk about time constants (50, 75 and 100us) which presumably define the frequency at which the pre-emphasis kicks in. Also, a slope of 6dB/octave is mentioned. Does this sound reasonable? Any comments appreciated.

Wilbert, ZL2BSJ.

Radio Shack says NO WAY.

With that said, I charge mine from the car's DC power jack (aka cigarette
lighter socket) wit regularity, but no ill effects. Polarity is tip positive.
The 9 Volt unit may work.

In a post WW2 edition Radio TV & Hobbies, there was an article on making crystals due to a shortage of manufactured ones.

The process was to heat a piece of lead (fishing sinker) in a crucible until melted and red hot (used a meeker burner to do this) then drop in some sulfur. Allow to cool then pull off a piece that looked different from the original lead.

Cheers
Graeme VK3JUD

You can buy several kits for less than $100.

Have a look at Dan's ~ "Small Parts" at http://www.fix.net/dans.html

He supplies two different kits for CW transceivers, as well as
otherwise hard to get parts for the homebrewer.

Personally I have built the NN1G Mark 3 transceiver for 80 m, and I'm
very satisfied with the kit.

Hi Guys. The trick with "feeding" NiCads is to limit their intake while charging, even from a car. You can use a Voltage regulator like a 7805 or 7812 for this by putting the regulator in series following the Input from the supply side and output to the battery with the ground post attached via a resistor to the output pin. The feed rate is calculated by I=Vr/R where I=current, Vr=VoltageRatingOfTheRegulator R=resistor so a 7805 with a 33 Ohm resistor in place feeds at a .151 Amp or 151ma. I do not know what the feed rate should be for those NiCads, but I am sure it is mentioned somewhere.

>code?

Transformers and other line operated devices connect to the chassis. A
chassis line connection (even a "ground" connection) requires the
chassis be isolated from any possible contact by the operator.

That's tough to do, especially since the connectors and relay control
jack are grounded to the chassis. That means the PA has to be a box
inside a box, with full low frequency ac and dc isolation.

The correct solution is simple. Don't connect power line operated
transformer primaries and such to the chassis. If 120 volts is needed,
use an isolated neutral lead from the outlet to the PA.

> How many analog/digital systems are around that have two or three
>levels of ground?

Plenty, but you won't find any UL/CSA/CE devices that have 120 vac
return through the case or any chassis to cabinet path where 120 volts
could harm the operator from a simple broken wire.

>Once inside the enclosure which is "grounded" can you run
>another rail?

That would be the way to do it, and keep the rail isolated from the
chassis. The rail could connect to a neutral lead that is isolated
from the chassis.

That way, if the neutral opens, the op won't get fried.

73 Tom

Tom:

Isn't the amp in a box in a box. The author has a chassis in a cabinet.
He has isolated the chassis and cabinet. Keeping the neutral and ground
separate. The chassis is bonded to the neutral and the cabinet to the ground.
He could have called the chassis a neutral rail and the cabinet ground rail.
I can see that the input/output jacks cause a problem with operator
contact.
With isolation transformer are you going to bond either side of the
secondary to the neutral or chassis, or just float the secondary?
The filament transformer could have had a 220vac primary. That would
have solved that.

In an amplifier that uses 240v single-primary transformers, Wes, neutral is
not connected in any way to the transformer windings. Thus, no current
flows through the neutral wire whether one or two stepstart resistors are
used. The safety ground/neutral wire is connected to the amplifier chassis
whether one or two stepstart resistors are used. What safety issues?

> THE NEUTRAL IS TIED TO EARTH AT THE SERVICE ENTRANCE.....

True.

After that, it is
> treated as a current carrying conductor.

NOT in the case described above. Please explain how the neutral could
carry fault current from the HV supply.

> The safety ground (what you
> should be tying to the chassis) carries fault current only, as John, WA0VYZ,

Distribution:

Tom:

He (designer) has put the chassis off from ground. If this chassis is in
another enclosure (cabinet) and the cabinet is ground has this violated the
code? How many analog/digital systems are around that have two or three
levels of ground? Once inside the enclosure which is "grounded" can you run

another rail?

From: k5dh@dlep1.itg.ti.com (Dean Hemphill K5DH)
Subject: WANTED: plug-in coil forms and sockets

I need at least two each of the old plug-in coil forms and sockets for
a CW transmitter project I'm working on (a 6V6 oscillator driving an
807 PA). Either 4-pin or 5-pin types would be fine, about 1-1/4" in
diameter or close to that.

I could also use a couple of Millen ceramic plug-bars and jack-bars for
my parts stock (future projects, y'know?).

ALSO... I need some B & W 3011 and 3015 coils (unused only, please) for
transmitter projects.

73 de K5DH! :)

Subject: (none)

In a post WW2 edition Radio TV & Hobbies, there was an article on making
crystals due to a shortage of manufactured ones.

The process was to heat a piece of lead (fishing sinker) in a crucible
until melted and red hot (used a meeker burner to do this) then drop in
some sulfur. Allow to cool then pull off a piece that looked different
from the original lead.

Cheers

It's pretty simple to build a 10min. timer with a 555 IC also, that way
when the radio is triggered after 10min you either have a CW id or voice
id.

Hi John --

Why would you want use an expensive GaAsFET in a 10 meter
preamp? There are plenty of good low-noise FETs or bipolar
devices that will do just fine up to and including two-meters.

Electrical distribution is a multiple-grounded neutral system. The neutral conductor is grounded at many points in the distribution. The safety ground in your house is local to your house. It does not go house to house. The safety ground is bonded to the neutral at one point, at the service entrance. The neutral is also grounded at the step down transformer on the pole (or underground). Your houses' safety ground is not for lightning protection.

major snip or two

I read something years ago about lead sulfide (?) crystals, being made
with plumbers lead and powered sulfer and a short chunk of 3/8 or 1/2
inch copper pipe. You melted this witches brew together and poured it
into the copper pipe, then cut it in half part way and broke it the rest
of the way off, leaving a ragged surface. Now,,, I have no idea what
the ratio was but it didn't seem like a really big problem at the time.
Let's see,,,, if you've never melted sulfer, or lead,,,,,,,, ah hell,,,
your on your own,,, sufice to say, bad things could really happen.

I've heard that silicon carbide can be used. The forward voltage drop
is a bit on the high side for a crystal receiver, but I remember seeing a
circuit using a "D" cell and a 1 meg pot to forward bias the silicon carbide
almost to the point of conduction. A very tiny radio signal could push it over
the edge.

Another interesting detector I have read about is called a "ticker".
Basicially it amounts to a small brass pulley on the shaft of a little motor.
One pole is a brass contact which slides on the face of the pully. The
other contact is composed of a piece of music wire or other springy wire,
which is laid in the groove of the rotating pulley, and kind of drags there. I
here tell that it is essentially useless for am, but that you can actually
hear cw morse code type stuff with it. (This is circa 1915-1920)

Still another involved a flat razor blade and a pencil lead. The blades are
(or at least were!) plated or or sputtered with a thin layer of something to
discourage corrosion. This in combination with a small piece of graphite
apparently creates a nonlinear junction - a diode if you will. I have my
doubts about the sensitivity of this device, but I suppose you could forward
bias it like the carbide and get more sensitivity out of it.

From: wk@killspam.frc.niwa.cri.nz (Wilbert Knol)
Subject: NBFM pre-emphasis, how much?

Thanks for reading this message.

I am in the process of nutting out a 2m xtal controlled TX strip to be used for packet. FM is obtained from a varicap diode across the xtal.

My question is: how much pre-emphasis (dB/octave) should I apply, and at what frequency should it start? My books talk about time constants (50, 75 and 100us) which presumably define the frequency at which the pre-emphasis kicks in. Also, a slope of 6dB/octave is mentioned. Does this sound reasonable? Any comments appreciated.

Wilbert, ZL2BSJ.

That is the worse imaginable way to get sceen voltage.

It is a very high IMD circuit.

The loading on the exciter varies with drive and screen current, since
the rectifiers load input RF on peaks ONLY.

I measured severa

Tom:

OK<OK I get it..... If he would not have bonded the one side of
the primary on any of the transformers to his chassis. This would have
been like running the neutral rail in a sub-feeder service panel isolated
from the ground. And would have been much simpler than isolating the
chassis. Would be no need for an isolation transformer then either, each of
the transformers would have been their own isolation.

There are 6 or 12 kits you can buy for $50-$100 that cover
part of one band. Multiple bands costs 2-3 times that figure.

The Norcal40a kit costs $129 and is the best.

ROB - GREAT - ignore the garbage. THANK YOU for posting those
pictures.
I LIKE To see hams' pictures and schematics. THIS is the kind of thing
the Internet does very well at.

The guys who complain are either -

1) Living in Russia and pay for their access by the kilobyte (yes this
is true!!)

or

2) Using a 286 that doesn't load stuff very fast!

Heck they can always push DELETE or IGNORE the articles, sheesh!

There is a french design, published in VHF communications, which was
supposed to cost about 100DM, and that was not just QRP. VHF
communications have a web page.

> -- proud members of the CQ family --

??? Of course it will work, you'll just need signals which are a bit stronger. The 1N34A has a barrier potential of about 0.2 V while the 1N914 will have a barrier potential of about 0.6 V. That'll require signals about 9.5 db stronger to overcome the threshold. In practice, that won't be a problem. Any signal strong enough to drive your headphones to a comfortable level will be strong enough to overcome the silicon diode potential barrier. You will miss some weak signals, of course. The best diode to use would be a point contact type like the IN21B used for years in radar receivers. Its barrier potential is slightly lower than either of the other types.

Now you *can* bias the diode to improve weak signal detection. That does require a battery (you can use a homemade "potato" battery), and a bias circuit. This will allow you to set the threshold arbitrarily close to conduction, and thus allow you to detect arbitrarily weak signals (radar receivers worked essentially this way before low noise SHF active devices became available). Of course the signals will be too weak to hear in the headphones without amplification. (In a receiver with very poor front end selectivity, such as the classic crystal set circuit, biasing the diode may bring on more troubles than it is worth since the selectivity will now be inadequate to avoid receiving virtually every signal on the band at once.)

Now if you allow a battery, then you could add an audio amplifier to boost the weaker signals so that they are audible in the headphones. But if you allow a battery and an active device, then you might want to go ahead and build a regenerative receiver. That's pretty simple too, and will normally perform better than a simple diode detector if the active device has adequate performance at the reception frequency.

(With a CK722, you'd stick with the biased diode and use the transistor as an audio amp at frequencies above about 2 MHz. With a more modern transistor (almost any small signal type), you'd do better to use the transistor in the regenerative detector circuit up through at least 60 MHz, and for most types, higher than that.)

Note that it is not impossible to make transistors at home, at least on the level of the CK722. There was a series of articles in the Amateur Scientist column of Scientific American in the early 1960s describing how to do it. (The hard part is refining the pure germanium or silicon wafer. The series showed how to build a zone melting refiner to do that.) It'd be easier to master glassblowing and make your own tubes, however. This definitely falls outside the competence of the typical crystal set builder, but might be of interest to someone looking for a *real* homebrew challenge.

Hi,

Can anybody give me any contact address of MAXIM for technical/designer's support?
I'm trying to design a Weaver method SSB Xciever using MAX2450 (51/52) quadrature modulator/demodulators. The built in LO is designed to work at 70MHz~160MHz. I need to make my radio work in the HF band. So is it possible to inject carrier into the Qmodulators from external oscilators? Has anyone tried this? Also will the Qmodulators/demodulators work properly (with external injection) at <30MHz & if possible as low as 1KHz? It took a long 2 months for my samples to arrive, so I don't want take any risks. Please help.

Thanks for reading.

Hi John,

Yes, that was my point. Sorry I didn't make it better.

Many things can be dangerous or complex, but why make something more
dangerous or complex than it needs to be?

Connecting any power line return path to the chassis is unnecessary.

The Sierra by NORCAL is more costly but you can add additional band
modules later on. The Ten-Tech is one of the least expensive (about
$90). This months QST has a 20 or 80 meter SSB QRP article - you can
purchase board, parts or a complete kit.

Type "QRP" in the search engines and you'll get lots of data.

Source record: 95712

I don't have a spec on the 2SC221, but I did check my NTE book. I does
cross to a NTE322. BUT!!! Unless their specs are wrong, the cross
reference is no good. First the case should be the same. In addition
to that, it lists the ft (where gain is only x1) as 100 Mhz. A long way
from 2M. Might make a good attenuator unless they really underspeced
the device!

Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew

Just read your post and wanted to comment on the articles dealing with tuner efficiency. There have been a couple of articles written in the past few years decrying the inefficiency of certain tuners and types of tuners, particularly when baluns are involved.

I suspect that certain balun designs may dissipate a large amount of power under certain conditions of mismatch. However, having used a Heath 2040 for about six years under some really terrible situations and having not "burned up" or even warmed up significantly the internal balun causes me to question the validity of the testing that was done.

The efficiencies measured using the tuners, such as the Tucker, in an unbalanced, balunless, configuration also causes me some problems. They are now telling me that the tuners that I have traditionally used, SA2040, Johnson Matchbox, no longer work as advertised.

Is this the result of new insight or new science? Or have I been lucky?

Further the proof is in whether you can: 1. use the tuner to provide an acceptable load to the transmitter output circuit. 2. transfer enough power to the antenna using the resulting configuration to enable communications.

My experience in both cases is that my tuners meet these objectives.

Another consideration in the vein of the "big picture" is that even if the tuner/balun efficiency is somewhat lower than thought, the use of low loss balanced feeders may still be more efficient than the use of standard grade RG213 under similar conditions of mismatch as seen by the balanced feeders. The Matchbox, being inherently a balanced device, would seem like the best way to couple to a balanced feed system sans balun, and should be far more efficient than other designs.

Ahemmm ... this mail list has more than 700 members by my
last reading! Most are paid subscribers and others are there during
the generous free trial period.

Here is another approach garnered from "deeper memory". ;-)

1. Make a small container of fresh molten lead, say 1/2" diam
and 1/4" deep.

2. While hot, sprinkle a very small amount of sulphur ...more
like specks ...on the fresh surface. Then allow to cool thoroughly.

3. For "catswhisker", make a small coil of piano wire with
sharply pointed end. Good electrical connections to the base of the
"ingot" and catswhisker are essential.

4. Apply pointed whisker experimentally on the surface of the lead ingot
for loudest signal.

Please don't ask me about the chemistry of this! It did
work (late 30's) but I succumbed to a 25 cent galena from some
mail order outfit. <VBG>

It is -- put together by someone who feels they have a cross to burn ...

or who wants to be seen as a hero of some sort amongst the faction who spent their only available $12.00 on a couple of six packs. The whole idea is ill advised and just dilutes the level of support and knowledge that would be available in one list with focused expertise and experience. Of course, there are people subscribing by the bezillions, but people would subscribe to lists on bologna and cheese sandwiches at an even higher rate. The possession of an internet ID and mail account is no guarantee of IQ .... Franky, having to subscirbe to 40 lists, each with the same basic members, but each focusing on narrow discussions of one manufacturer or whatever to get the breatdth of BA discussion is useless. Maybe I should start a list devoted to Hammarlund equipment manufactured between 8:02am and 9:22am on March 22, 1956 ?
Its all an ego trip of major proportions ...

;-)

The 9120-0026 is not listed in the !973-74 replacement parts catalog. The numbers 0016,0018,0022,0028, are listed, but no 0026. They are all refered to as AF transformers. That's all I could find. 73 Tom WB6IQD dunnt@cco.caltech.edu

Don't misunderstand what Tom is saying. He's talking about grounding
a filament transformer *primary* winding to chassis. Of course there
can be good reason to tie one side of the transformer *secondary* to
chassis.

The same circuit (if it is the one I think it is) also ties 220 VAC
neutral to chassis. That's a violation of standard wiring practices
and can defeat GFI protection circuits.

>transceiver which could be adapted to 27MHz citizen-band use?

If you were in the US, I'd tell you no, since A1 transmissions are
not allowed in our CB radio service (pity).

Why not just use a CB transceiver? Try keying the B+ into the final
stage (press the PTT with one hand and use a keyer to key the B+ with
your other hand). You'll have to add a BFO to the receiver, but that's
easy to do.

Thor,
I built one last spring and LOVE it! I only spent about 6 hours
building it, some guys take 15, but my 6 hrs was also mostly in front
of the TV... I've worked a lot of guys on it and used it for FD last
year. The only problem for FD is that when the sun gets real hot (I'm
in Texas) the rig drifts a little bit with the temperature change. I
don't consider it a problem, it was fine with a bit of shade. The
case is dark blue, and it probably got up to 130 or 150 degrees F.

Go for it, you won't be sorry. The kit is good quality, and has
excellent instructions. It's not the "part A in slot B" like
Heathkit, but if you know a capacitor from a resistor, you can do it.
You have to wind a few toroids,but they are all small except the 60 or
so turns for the VFO.

Have fun,
Kerry Miller

Hi Gary!

I will admit that 1N914s or 1N4148s will work after a fashion,
but stand by my statement that they are the worst possible choice
for a crystal set.

I have over 30 vintage crystal sets, including some rare English
models from the 1920s and a few commercial loose couplers.
I have several modern homemade cyrstal sets designed for AMBCB dxing.
They even include S-meters -- 20-uA meters in series with the
headphones to measure the detector current to assist with tuning..
I use early Baldwins with mica diaphrams since those 1920s headsets
are the most sensitive ones I have been able to find. (Run of the mill
Brandes are a close second, however!) I use a good ground
and toploaded (radial) 60 foot vertical for an antenna.

My more elaborate homebrew sets have three stages of tuning, with
variable coupling, and were made for AMBCB dxing. To get any selectivity
much above 1000 kc requires light coupling, and you can't afford to
throw away 9.5 dB and expect to hear anything except for the strongest
local signals. My sets are good enough to seperate stations within 30 kc
of each other in the 800-kc region, and I can easily receive stations on
1030 kc
and ll30 kc with WTIC some 30 miles away running 50kW on 1080.
I have over 100 dx stations logged to date on one of these sets.
I would kill for another 10dB of signal!!!!

I have never much luck using a 1N914 diode, and I have tried
various biasing schemes to improve their performance as detectors.
I have used everything from razor blade detectors and some of my vintage

carborundums with better results. The 1N914 is a waste of time for anyone who is SERIOUS about building crystal sets. Unfortunately, when someone mentions crystal sets, most folks think of toys.

Subject: 2SC2221 ---> NTE322??

Hi folks - I melted the 2SC2221 transistor in the final amp of my
Tempo S1 HT. Honolulu Electronics says that a replacement for the
2221 is an ECG322, and a replacement for that is an NTE322 (which
is what they sold me).

Two things bother me:
1. The 2SC2221's case was similar to a TO-39 (round, metal); the
case was soldered to the circuit board ground (for heat dissipation
I suppose). The NTE322's case is similar to a TO-220 and is plastic.
Should the NTE322's metal stub be soldered to ground?
(i.e., are the 2221 and 322 electrically identical? I'd hate
to ground the case if its not meant to be.)

2. The small amount of data that came on the 322 package says:
"NPN - Si, RF Pwr Amp, CB, Po 3.5W Min, 27 MHz"

This 2m HT (with the original 2SC2221 PA) was rated at 1.5W output.
Can I exppect the NTE322 "CB PA" to have a similar output at 2m?

Thanks in advance!
Jeff KH2PZ

>reason for using bare/tinned copper wire (RF signal handling etc.)? TIA

> 73 de Laurens

The tinning handles RF slightly, but has offsetting problems when the
surface begins to passivate.

Generally, the only reason I use tinned wire for a big RF coil is to
make it easier to solder a tap in place when the coil is already
installed. Scraping can be a **** then.

For real fine tuning of a coil of that sort, you often want it in
circuit, surrounded by all its chums before final placement of taps.

Hope this helps.

There are 6 or 12 kits you can buy for $50-$100 that cover
part of one band. Multiple bands costs 2-3 times that figure.

The Norcal40a kit costs $129 and is the best.

Subject: HELP! MAXIM MAX2450 /51/52

Hi,

Can anybody give me any contact address of MAXIM for technical/designer's support?
I'm trying to design a Weaver method SSB Xciever using MAX2450 (51/52) quadrature modulator/demodulators. The built in LO is designed to work at 70MHz~160MHz. I need to make my radio work in the HF band. So is it possible to

inject carrier into the Qmodulators from external oscilators? Has anyone tried this? Also will the Qmodulators/demodulators work properly (with external injection) at <30MHz & if possible as low as 1KHz? It took a long 2 months for my samples to arrive, so I don't want take any risks. Please help.

Thanks for reading.

Subject: Home made crystal(?) radio

I remember reading about making a detector using a penny (or other piece of metal) and touching a thin wire to it (the cat wisker). It appears that any corrosion on the surface will give the non-linear contact. I've never tried it, but I remember reading about it - maybe 20 years ago. Good luck.

>Senior Technical Editor, Communications Quarterly Magazine
>"The Radio Connection," Popular Communications Magazine
> -- proud members of the CQ family --

??? Of course it will work, you'll just need signals which are a bit stronger. The 1N34A has a barrier potential of about 0.2 V while the 1N914 will have a barrier potential of about 0.6 V. That'll require signals about 9.5 db stronger to overcome the threshold. In practice, that won't be a problem. Any signal strong enough to drive your headphones to a comfortable level will be strong enough to overcome the silicon diode potential barrier. You will miss some weak signals, of course. The best

diode to use would be a point contact type like the IN21B used for years in radar receivers. Its barrier potential is slightly lower than either of the other types.

Now you *can* bias the diode to improve weak signal detection. That does require a battery (you can use a homemade "potato" battery), and a bias circuit. This will allow you to set the threshold arbitrarily close to conduction, and thus allow you to detect arbitrarily weak signals (radar receivers worked essentially this way before low noise SHF active devices became available). Of course the signals will be too weak to hear in the headphones without amplification. (In a receiver with very poor front end selectivity, such as the classic crystal set circuit, biasing the diode may bring on more troubles than it is worth since the selectivity will now be inadequate to avoid receiving virtually every signal on the band at once.)

Now if you allow a battery, then you could add an audio amplifier to boost the weaker signals so that they are audible in the headphones. But if you allow a battery and an active device, then you might want to go ahead and build a regenerative receiver. That's pretty simple too, and will normally perform better than a simple diode detector if the active device has adequate performance at the reception frequency. (With a CK722, you'd stick with the biased diode and use the transistor as an audio amp at frequencies above about 2 MHz. With a more modern transistor (almost any small signal type), you'd do better to use the transistor in the regenerative detector circuit up through at least 60 MHz, and for most types, higher than that.)

Note that it is not impossible to make transistors at home, at least on the level of the CK722. There was a series of articles in the Amateur Scientist column of Scientific American in the early 1960s describing how to do it. (The hard part is refining the pure germanium or silicon wafer. The series showed how to build a zone melting refiner to do that.) It'd be easier to master glassblowing and make your own tubes, however. This definitely falls outside the competence of the typical crystal set builder, but might be of interest to someone looking for a *real* homebrew challenge.

Shack, Maxon, and Midland plan to make and market these radios for the foreseeable future.

Many models of Citizen's Band (CB) receivers on the market now have a WAT feature built into the unit. You can be monitoring any CB channel and if the WAT is detected on the weather radio channel you have set on the unit, the unit will activate a weak tone and switch the unit to the weather radio.

Hopefully you have seen the writeup I did on the reasoning for placement of the WAT in the coding sequence. If not, let me know and I'll forward a copy. In the SAME environment, the WAT will continue to have a function if for no other reason than as an attention signal to the listener.

Subject: Re[2]: 1050HZ Warning Alarm Tone

The transmitter operates in the narrow band of FM (25 KHz channels). Modulation in this band is confined to +/- 5 KHz of the primary frequency leaving a 7.5 KHz guard on either side of the max. deviations. The audio level from the program console is supposed to deviate the transmitter at a minimum of 4.25 to a max. of 5.0.

We are finding that all over the country, many of our systems are not operating to that standard. We are not really sure how wide spread the problem is but we are taking steps to correct it. If you find the deviation below these stated levels, do not hesitate to call the NWS office and let them know.

Unlike the broadcast industry that uses some very high quality lines or RF Studio to Transmitter Links (STL), we use mostly voice grade telephone lines and the attenuation on these lines can vary. I will pass you comments and concerns on to the appropriate people there in the NWS.

Subject: Re[2]: 1050HZ Warning Alarm Tone

Please do let us know if you observe a problem with a system. We are in the final stages of developing a remote monitoring system but it is still a few months away so the eyes and ears of users such as yourself are appreciated.

Radio Shack says NO WAY.

With that said, I charge mine from the car's DC power jack (aka cigarette
lighter socket) wit regularity, but no ill effects. Polarity is tip positive.
The 9 Volt unit may work.

>another enclosure (cabinet) and the cabinet is ground has this violated the
>code?

Transformers and other line operated devices connect to the chassis. A
chassis line connection (even a "ground" connection) requires the
chassis be isolated from any possible contact by the operator.

That's tough to do, especially since the connectors and relay control
jack are grounded to the chassis. That means the PA has to be a box
inside a box, with full low frequency ac and dc isolation.

The correct solution is simple. Don't connect power line operated
transformer primaries and such to the chassis. If 120 volts is needed,
use an isolated neutral lead from the outlet to the PA.

> How many analog/digital systems are around that have two or three
>levels of ground?

Plenty, but you won't find any UL/CSA/CE devices that have 120 vac
return through the case or any chassis to cabinet path where 120 volts
could harm the operator from a simple broken wire.

>Once inside the enclosure which is "grounded" can you run
>another rail?

That would be the way to do it, and keep the rail isolated from the
chassis. The rail could connect to a neutral lead that is isolated
from the chassis.

That way, if the neutral opens, the op won't get fried.

From: jstroppe@uhl.uiowa.edu (John Stroppel)
Subject: Soft-start circuits

Tom:

Isn't the amp in a box in a box. The author has a chassis in a cabinet.
He has isolated the chassis and cabinet. Keeping the neutral and ground

separate. The chassis is bonded to the neutral and the cabinet to the ground.
He could have called the chassis a neutral rail and the cabinet ground rail.
I can see that the input/output jacks cause a problem with operator
contact.
With isolation transformer are you going to bond either side of the
secondary to the neutral or chassis, or just float the secondary?
The filament transformer could have had a 220vac primary. That would
have solved that.

Subject: UHF PA-Module

UHF Power Amplifier Modules

The MITSUBISHI M67729H2 has been developed and produced in large
quantities
for UHF cellular telephone applications.

Technical Data:
Output Power = 20 W
Gain = 21 dB
Harmonics = -40 db
Spurious Outputs = -70 dB
50 Ohm in/out

This module is also excellent suited for class C Amateur Radio PA's in the
70 cm-Band.
The low output of a UHF handheld may be amplified to about 20 W output! The
use of these modules is the easiest way to build a PA. There are various
discriptions in the ham literature.

I am now able to offer you this excellent module with a more than 10 dB!
price
reduction:

1 ea for DM 35,--
10 ea for DM 300,--

Just FYI, it's a 600 ma battery pack, so C/10 charge rate is 60 ma.

To further qualify my response from yesterday:

I charge my battery packs with regularity from the car. BEFORE I did this for the very first time, I did some investigation. LOOK AT THE SCHEMATIC. There is a voltage and current limiting circuit BUILT INTO THE BATTERY PACK. I took mr. ammeter out to the car to verify. Yep, drawing a mighty 57 MILLIAMPS when powered from the lighter socket. The circuit works as expected. All is well in the world.

Of course, RS will tell you not to do this.

So, back to which adapter - go with the 12 Volt unit. And don't listen to anyone that tells you that much current will blow your pack. Just because a DC adapter is CAPABLE of providing 1 Amp does not mean that it will FORCE 1 Amp through the circuit. It just means that you: a) Have an adapter that will run cool while charging the battery. b) Have an adapter that can, theoretically, recharge 15 packs at once.

Good luck, 7 3, YMMV, etc.

Hey guys - I wanted to let you all know that I have found a really
great web site for homebrew articles and projects on-line
that I think many of us do not know about!

It is a branch of the G3YCC QRP page in England that has
SM0VPO's projects:

http://www.gqrpclub.demon.co.uk/sm0vpo_1.html

Give it a try. There are numerous tube and transistor transmitters
and receivers shown there. Really great!

I hope you find it interesting as I did!

==========
You would need to set up a metering circuit for tests. One fail-safe
way to charge NiCads is to charge them for 15 hours at a rate of
one-tenth the design capacity.

If the charge rate you observe is in this 10% ballpark, just calculate
how long it will take to put in 150% of its rated capacity, and go
with that when the cells are fully discharged.

NOTE: The ratings on your charger do not indicate that it somehow
"forces" that much current into the load - it merely indicates the
rating beyond which you can expect it to fail internally. The amount
of current which flows in the circuit depends on the circuit, not the
"rating" of the charger. This is why you must actually set up and
measure it. Got a meter? Get one. Got a callsign? Use it with your
posts.

Hi

I have used a so-called "Farmans" pickle-jar as a VERY effective chimney for my 3-500 50MHz amp. The bottom of the jar has to be cut away with a glass cutter and the necked portion of the jar fits the contour of the 3-500 beautifully.

Be sure to CAREFULLY sand the bottom of the cut portion to eliminate the sharp edges. Check out the jars at your local grocery store!

From: Woody White <"eMail "@my.www.page.Mailto>
Subject: 2SC2221 ---> NTE322??

I don't have a spec on the 2SC221, but I did check my NTE book. I does
cross to a NTE322. BUT!!! Unless their specs are wrong, the cross
reference is no good. First the case should be the same. In addition
to that, it lists the ft (where gain is only x1) as 100 Mhz. A long way
from 2M. Might make a good attenuator unless they really underspeced
the device!

From: ajass@tabaqui.informatik.rwth-aachen.de (Andreas Junklewitz)
Subject: Cryptic coil description

Hallo,

in one of the ARRL-Microwave handbooks, there are coil description
which are absolut cryptic to me.

What means: 4t, 28 swg e.c.w. ?
or 2.5t, 28 swg t.c.w. ?

I guess the t stands for the number of turns. But what is the rest?
Any hints are appreciated.

With best regards
Andreas

Thor,
I built one last spring and LOVE it! I only spent about 6 hours
building it, some guys take 15, but my 6 hrs was also mostly in front
of the TV... I've worked a lot of guys on it and used it for FD last
year. The only problem for FD is that when the sun gets real hot (I'm
in Texas) the rig drifts a little bit with the temperature change. I
don't consider it a problem, it was fine with a bit of shade. The
case is dark blue, and it probably got up to 130 or 150 degrees F.

Go for it, you won't be sorry. The kit is good quality, and has
excellent instructions. It's not the "part A in slot B" like
Heathkit, but if you know a capacitor from a resistor, you can do it.
You have to wind a few toroids,but they are all small except the 60 or
so turns for the VFO.

Have fun,
Kerry Miller

From: Ed Loranger <loranger@sr.hp.com>
Subject: Help wanted for the Pixie-2 Transceiver

Hey! That's great your building this rig. I've
found very little information on similar, simple
projects for QRP. I've been all over the net
and most everyone wants you to BUY!

I would go ahead and put it in. This inductor
will most likely improve response in the 80 M. band.

If you wish, use a small low frequency torroid
and wind 6-10 turns of 22 AWG wire on it and see
what you get. It worked fine for me with 6 turns.

As a direct conversion receiver/xmtr, you'll notice
the oscillator beat on a nearby receiver. Also you
will probably get a nearby AM Radio Station if you dont
change the output capacitor to 100 pf. You absolutely
must use a resonant wire with this one. I found that
a 66 ft end fed or a dipole with 33 ft. legs works great.
If you play around with a short antenna you'll think
there's something wrong -- the local AM broadcast station
will be overpowering! Don't do any troubleshooting
until you've got it hooked up right.

One more thing, the keying wire is in series with
the output/mixer transistor and the DC resistance of
a long connection to the key will adversely affect
output power. Keep it short or start looking for
a switching transistor to bypass the 10 K ohm idling
resistor (it is used for receive mixing).

If you need any more information I can email
you the original circuits and a 700 Hz RIT/XIT mod
I found on the web. Unfortunately the mod forces
a +/- supply, requiring another battery.

My Heath transmitters are wired that way. If a filament was above
ground potential couldn't that adversely effect the operation of the
tube? Electrons boiled off the cathode might flow towards the
filament instead of the plate.

Hi name is Barry/WB5SEG

Looking for any projects for the FX-146. Like tone device for repeaters, more channels. Just put it together and Iam already looking for extra stuff for it.

Another odd thing I noticed. That listserver wanted a confermation (by replying to a message it sent) to complete the subscription process. Seems to be low traffic at the moment (99 members) but that may change...

Garbage? You mean ignore the rules dont you Carling? Are you a "newbie" too?
I don't live in Russia and I have a 486 computer with 28.8 modem connection that works quite well. There are thousands of us that use offline news group readers that automatically download the news group articles.

Dont you understand that if the practice of posting MASSIVE binaries here on this TEXT ONLY DISCUSSION group proliferated that the burden on the servers and readers would impede the exchange of meaningful info? There are mechanisms in place to exchange the pictures and schematics that you and Rob desire to do. Do it there and both of you keep your flawed logic and pictures to yourselves!!! Geeez...

Got two SS5702 Jiwatsu,
Dual Trace,
DC-20MHz,
4" X 3" blue display,
Backlit graticule,
10 V to 1mV settings,
with calibrate settings,
bought used, works fine,
nice.

Would like to get $200.00 for one of them.

If you would like to make a reasonable offer
reply via email only, stiwari@cwonders.com

Tnx

I BELIEVE HE OR SHE WANTED TO MAKE THEIR OWN PARTS
FROM AROUND THE HOUSE.

That being the case, buying anything would be a faux pas.

Try, instead, a piece of copper ANYTHING, like the copper bottom
of a cookpan, and a drop of vinegar, and a little metal tab to lay on
it after the vinegar dries. I think we did something like that when I
was in grade school, but after that they discovered dirt and kids lost

interest in mere science.

It wasn't THAT long ago, but i have a hazy memory that was how we did
it.

Hope it helps.

Hi Tim

My crystal sets are more made for dxing, and have a bit of inherent loss.
The 1N914/1N4148 silicon WILL work, but weak signal detection will
suffer because of the higher barrier voltages.

3453. most linear transistor?

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-03-27 00:00:00 UTC
From: stoskopf@tri.NET
Message-ID: <3339EA0F.4E00@tri.net>
Source record: 95616

Am rebuilding my homebrew RX and wondered if anyone has a comment on the most linear transistor available for use in the post-mixer amplifier. I'm currently using a VMP-4 FET with 28 v. and biased at 100 ma. and have no real indication that I should change, but after 15 years...

The Motorola TPV590 looks good, but the thought of using a 900 MHz device at 9 MHz or 455 KHz seems a bit of a stretch. The class A dissipation would be the same as the VMP-4 in my application.

Has been legal since the late 70s when crossband rptrs were made legal..
I operated a crossband 220-10mtr FM box in 1978 ....WR5AOK was my rptr
callsign at the time (just before it expired)...
BUT the 10 mtr side MUST be within the 29.5-29.7 rptr subband AND the
callsign of IT must be general or above....YEs Novices on 220 can be
crossbanded to 2 and 10 mtr FM rptrs!

Here is another approach garnered from "deeper memory". ;-)

1. Make a small container of fresh molten lead, say 1/2" diam
and 1/4" deep.

2. While hot, sprinkle a very small amount of sulphur ...more
like specks ...on the fresh surface. Then allow to cool thoroughly.

3. For "catswhisker", make a small coil of piano wire with
sharply pointed end. Good electrical connections to the base of the

"ingot" and catswhisker are essential.

4. Apply pointed whisker experimentally on the surface of the lead ingot
for loudest signal.

Please don't ask me about the chemistry of this! It did
work (late 30's) but I succumbed to a 25 cent galena from some
mail order outfit. <VBG>

yes om - this is the gated screen linear configuration first
described by G2DAF/ZL1AAX/W6EED etal in early sixties. Amp hr with
two 4cx250B's has been running fb for over thirty years. A few
other old hams i know still run this type of amp with no problems.

Neet circuit but takes tinkering to get the griddrive/Vsg ratio
correct for a particular type of tube. Benefits are no bias or
screen supply needed, and requires very little drive. Hr 20-40
watts drives it to 1kw input easy. Plate efficieny hr is about 75%.
Also, there is no chance tubes can run away. Downside is swamping
excess exciter power out, if you can't set it lower than the
ubiqitous 100 watts.
This is not for the kit-builder or follow-the-other-guy's-circuit
exactly! Many hams tried this early on with dismal results.
But - If you have a pretty solid tech background and want to mess
with it, let me know.

Hi John,

If you are happy with that PA, I suggest you never put it on a two tone test system and measure IMD at varying power levels.

The real rub with this design is that all the energy is extracted at the crest of the sine wave, and the peak current is very high. That means the exciter sees a very low load impedance at peaks, and a much higher impedance as RF voltage is less than peak. This effect results in envelope distortion by uneven exciter loading.

The very reason class AB2 PA's use heavy negative feedback or swamping resistors is to eliminate this peak load chage, yet the G2DAF system makes it worse!!!

As a second thought, it is much better to run the screen off its' own supply. Screen regulation is critical for good dynamic IMD performance (although a fixed level two tone test can be made to look good even in a "ratty" class C amplifier at one power level), and the G2DAF circuit operates with screen voltage that varies at a syllabic rate.

Any phase lag between the screen voltage and RF envelope level will always result in distortion of the output envelope. That is because the peak screen voltage lags the peak RF input envelope by the charging time, and the declining envelope slope has screen voltage above the level of the increasing envelope slope.

The reson for the envelope shape distortion is the self-rectified system charges the screen capacitors through the source impedance of the exciter, and it discharges the capcitors through the screen current, so there is always phase lag in the screen voltage system.

When that is coupled with the peak loading of the drive signal, the result is a potpourri of IMD producing effects in the G2DAF system.

A person without a rack of test equipment and experience at measuring IMD is better off to avoid circuits that have many variables potentially causing poor IMD performance.

When I measured several PA's using the G2DAF system at the request of a manufacturer, the result was totally unacceptable IMD performance. I'm sure that is why the circuit never became accepted commercially.

Your radio dealer can assist here, the book titled " Radio / Tech Modifications " is accurate and avaliable at 818-843-4080. ICOM can assist, but ICOM REQUIRES a copy of your MARS or CAP license before they will give out the information. ICOM prefers you approach the Dealer or MARS information officer for this information. Some of the newer ICOMs are coming already able to transmit from 140 to 150 Mhz so a MARS modification is no longer needed as the radio will operate MARS / CAP right from the box.

Gary

Hi

I have used a so-called "Farmans" pickle-jar as a VERY effective chimney
for my 3-500 50MHz amp. The bottom of the jar has to be cut away with
a glass cutter and the necked portion of the jar fits the contour of the

3-500 beautifully.

Be sure to CAREFULLY sand the bottom of the cut portion to eliminate the sharp edges. Check out the jars at your local grocery store!

Hi Gary!

I will admit that 1N914s or 1N4148s will work after a fashion,
but stand by my statement that they are the worst possible choice
for a crystal set.

I have over 30 vintage crystal sets, including some rare English
models from the 1920s and a few commercial loose couplers.
I have several modern homemade cyrstal sets designed for AMBCB dxing.
They even include S-meters -- 20-uA meters in series with the
headphones to measure the detector current to assist with tuning..
I use early Baldwins with mica diaphrams since those 1920s headsets
are the most sensitive ones I have been able to find. (Run of the mill
Brandes are a close second, however!) I use a good ground
and toploaded (radial) 60 foot vertical for an antenna.

My more elaborate homebrew sets have three stages of tuning, with
variable coupling, and were made for AMBCB dxing. To get any selectivity
much above 1000 kc requires light coupling, and you can't afford to
throw away 9.5 dB and expect to hear anything except for the strongest
local signals. My sets are good enough to seperate stations within 30 kc
of each other in the 800-kc region, and I can easily receive stations on
1030 kc
and ll30 kc with WTIC some 30 miles away running 50kW on 1080.
I have over 100 dx stations logged to date on one of these sets.
I would kill for another 10dB of signal!!!!

I have never much luck using a 1N914 diode, and I have tried
various biasing schemes to improve their performance as detectors.
I have used everything from razor blade detectors and some of my vintage
carborundums with better results. The 1N914 is a waste of time for anyone
who is SERIOUS about building crystal sets. Unfortunately, when someone

mentions crystal sets, most folks think of toys.

Silicon diodes typically have a higher conduction voltage than Ge.
But, how 'bout a "hot carrier" diode?

Hi Tim

My crystal sets are more made for dxing, and have a bit of inherent loss.
The 1N914/1N4148 silicon WILL work, but weak signal detection will
suffer because of the higher barrier voltages.

It's more than one. I don't have either the rig or manual at this
location yet, they are with the programmer, but I'll detail what
was different as soon as I can.

Maybe I'm picky, but I called ICOM to verify the manuals, and
specifically
asked for addendums or changes, and was told there were none.
Much hair pulling later, they remembered this tech manual with
what they called "the old codes" and claimed the manual
documented the "new codes".

All I know at this point is the programmer is running just fine now,
and I expect a beta version probably next week.

Just another note:
About 20 years ago I was converting a WW II receiver to solid state and initially replaced the tube diode detector with a Si diode (1N914 I think). I thought something had broken! Although the solid state diode was more efficient overall (no filament or plate voltage needed) it had much less output than the tube. When I switched to a Ge diode (1N270) the signal came up dramatically! I was loosing over half of my signal in the Si diode! I decided to stay with the Ge unit for simple AM detectors.

The Si diode has a faster switching rate than the Ge unit and theoritically works better at higher frequencies (I've never tested this myself but everything I've ever seen written supports this.) so it's a better choice when making a balanced mixer, product detector, etc. There are other diodes (hot carrier, etc.) that are even better choices in more

modern equipment.

If you follow the diode detector with an audio amp with sufficient gain you can compensate for using a Si diode rather than a Ge diode detector to a great extent. I've built several direct conversion receivers using an oscillator feeding a balanced ring mixer (made from 1N914 Si diodes) and followed by sufficient audio amplification. These have worked very well for me.

However, I'd expect you'd still loose the weaker signals in an AM detector reciever. My experience agrees with what K1ZJH said.

There are many kinds of materials that will provide rectification/detection of an AM signal. Consider rusty rain gutter connections that can generate TVI. These work well in moderately strong fields but don't do well on signals from across the pond. My point is that some materials are better choices than others even when all will work to some extent.

: 60s and the dammed transformer is arcing over.

Why not try rewinding it? Separate the plates, and unwind the burned wire. Measure the lengths of the windings which you have removed and rewind with the same length and gauge magnet wire. Coat the plates with shellac when reassembling and bolt together tightly. It is pretty straight forward (albeit a bit boring).

Defeat GFCI's? All the ones I've measured would be tripped immediately
by a neutral that's grounded past the GFCI; they try to excite a ground
loop (and trip if they succeed to the tune of 10mA or so). But...how
many hams run their rigs on GFCI-protected circuits??

To dig up an old thread, are you (Roland) still around here? Found your message on DejaNews and was wondering what device/supplier you used for your LCD panel. I've got a 770-1290 MHz DDS/PLL synthesizer working on the bench for a general-coverage VHF/UHF receiver project, and will soon need to tackle the frequency-display part of the problem. The receiver will basically be "run" by a dedicated PC-compatible motherboard, so I'd like to be able to connect the display panel directly to a serial or parallel port.

Anyone else have any good sources for high-legibility LCD panels that can be updated directly from a PC serial (actually, parallel would be better) port? I don't need color, dot addressability, etc., but at least 4-5 lines by 64 characters would be good. The main thing I want is ultra-high quality readability and backlighting -- similar to what you'd see in a good-quality test instrument.

Hi Rob

Enjoyed your message about high performance homebuild receiver.
I'm working on such a project since many months (years??).Here are some comments and questions on the subject :

1.Preselector . What about insertion loss and selectivity of your circuit (especially on the upper ham bands).
I merely build band pass filters centered on each ham band (present status is 14 MHz only!!) so I'm interested in any ideas and comments about good front end selectivity .

2. Front End . No comments .I'm using Makhinson ideas .

3. IF Filters and amplifiers . Your approach seems very smart but what about Q degradation by the varactors and AGC stability problems related to this structure .
Here I use home made ladder filters (12 poles for main and 4 poles for noise) I designed with the Hayward and Makhinson methods.
The band pass is around 2300Hz and shape factor in the order of 1.6 (6/80dB).I have also build a 1700Hz unit and designed a 400Hz one).

I agree with you that narrow filters build around common (and cheap) crystals are associated with high insertion losses .
The present amplifiers are MC1350 chips but I recently ordered AD600 and AD603 in order to experiment the Carver and Analog Devices schematics . I hope to improve the AGC behaviour through the use of the "linear in dB" gain control characteristic .

4. Local oscillator . For the first tests I use a classical Colpits VFO but I'm working on a DDS/PLL synthesizer (according to Rhode works). The DDS build around an AD7008 controlled by a 80C552 microcontroller is now operational:tuning is made by an HP optical coder and frequency is displayed on an LCD panel .
The PLL part has to be build : I am interested in any comments or advices you could made about the Rhode paper.

5. Product detector and Audio amp. The product detector is a classical diode DBM . I made tests with the sample and hold technique proposed by Rhode (QST Nov92) but the detector dynamic range improvement of this circuit was not as high as expected . Any comments about this method would be appreciated.
My audio amplifier is an ugly one and I suspect that great improvement in A.F quality could be obtained !!!

This receiver forum is really fascinating !!!

The bias network has to present a *very* high impedance load to the circuit in order to work. But it will work.

The 9 should work just fine. The trick is, the battery pack has its' own
built-in voltage regulator for the 6 AA-sized ni-cad cells. Yeah, if you
can feed it 9.5v, it'll work. And I have also plugged the car's DC straight
in. As long as the LED glows, it'll work.

3489. Squelch Pop Suppression on Motorola

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-03-28 00:00:00 UTC
From: thompson@pdnt.com
Message-ID: <5hfitm$855$2@sol.pdnt.net>
Source record: 95504

I have two Radio Shack PRS-102 UHF tranceivers which I believe
are the same/similar to the Motorola Sport 10x, except they
broadcast on GMRS frequencies 462.xxxx MHz.

Anyway, the problem I have is that I'm trying to hook up my own
speaker any microphone to them. When one of the tranceivers picks
up a transmission and activates the speakers, it's proceeded with a
'pop' sound. This isn't a problem unless one puts a speaker or ear
bud near ones ear. Next to one's ear this pop can become painful
quickly. I'm wondering if there is some way to absorb this initial
pop... Is there some simple circuit I can stick in here? Any leads
would be most appreciated.

Also, this tranceiver has a 1/8" and a 3/32" plug. The 1/8" is appears
to be the speaker out and the 3/32" is the mic in. I'm under the
impression that it is possible to get the tranceiver to turn on
transmission through these two jacks, however I don't know how it's
done.... that is remotely pressing the transmit button. I've tried
various combinations of shorting, with no luck. any ideas?

Thanks for any info you can send my way,

Dave Thompson

3490. MJ11012 Pins

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-03-28 00:00:00 UTC
From: don.phelps@infoway.com
Message-ID: <859516841@infoway.com>
Source record: 95505

I am designing a screen supply for my old SB-102 pair of 6146B.
I am raising the screen voltage from 150 to 200.
I have a 1 watt 200 volt zener, a 50,000 ohm droping resistor,
and a MJ11012 darlington NPN rated at 400 volts 15 amps,
175 watts. I am series regulating 300 volts down to 200 with
just the screens as a load.

1. Please someone tell me the pins on the TO 3 case.

2. I calculate the circuit as follows.
Max screen pissipation is 3 watts, or 6 watts for a pair.
At 200 volts, that is 0.030 amps. The gain of the parlington
pair is minimum 100, maybe 2K. So very little currant is needed
in the base for the load.

3. My 1 watt 200 volt zener can pass 1/200 or .005 amps.

4. Using a 50,000 ohm droping resistor from 300 volts to the zener
to ground provides a drop of 100 volts at 100/50,000 or .002 amps.

5. Now I connect the collector to 300 volts (the case?) the
200 volts to the base (which pin?) and get a stiff 200 volts at the
emitter (which pin?).

6. I am hoping to get about 190 watts per pair with the screen
increased from 150 to 200. I now get about 110 to 130 watts out.

I've heard I should have a blower over the finals sucking air up and out.
Any other suggestions?

Dear All,
I am trying to obtain newer roms for my ancient PK232. This is a non MBX one, one of the very old ones. It has two proms labelled dec 88.

Does anybody have any newer roms, if they have the data I could burn them myself.

This note was *only* for the handful of folks sub'd to the old
Glowbugs list (whose host site was asking a yearly fee from each
reader); Conard will subscribe them by hand. This note wasn't meant
to be a public invitation to email him and have him do all the subs
manually.

> as a boy experimenting with xtal radios.

I remember building a "fox hole" radio from plans in a children's science book when I was a kid. It used a broken pencil "lead" tied with thread to the end of a safety pin, with the point of the lead resting on the beveled edge of a razor blade for the crystal. The head of the pin (bent to about 120 degrees) and the razor blade were fastened to a block of wood with thumb tacks. This connected to a coil made around a toilet paper tube and then to a cheap crystal headphone. I remember having to move the pin around ever so slightly on the razorblade edge until I started picking up a signal. Only problem was it picked up all the local stations together. I'd like to find the plans again and make it again with the kids. Has anyone come across this who can direct me to the plans (or even post them here)?

3515. PC card transceiver project

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-03-29 00:00:00 UTC
From: David Nye <nyeda@uwec.edu>
Message-ID: <333CD922.6AA2@uwec.edu>
Source record: 95530

I just got my tech ticket a couple of weeks ago with my son and we've decided we want to try building a second 2M transceiver. The ARRL Handbook describes some one-chip receiver and transmitter chips, the Motorola MC3363 and MC2831A and a similar Phillips receiver chip the NE627 that we're considering using. We're planning to build it on a PC card so we can use the PC for control, audio out through the sound card, and use the PC's power supply. Obviously we'll need to be careful about shielding the board and use an outside antenna (and wire-wrap is out).

Has anyone worked with these chips or built a transceiver on a PC card? There is a SWL radio available on a card so it must be possible to overcome the noise problem. Any words of wisdom?

David Nye KB9PSL Eau Claire, WI

Hello Steve,

We buy these exact items from RF Connection:

The R.F. Connection
213 N. Frederick Ave. Suite 11-W
Gaithersburg, MD 20877
USA

Tech Support (301) 840-5477
Orders (800) 783-2666
24 hour Fax (301) 869-3680
e-mail rfc@therfc.com

http://www.therfc.com

They are honest, competent and a pleasure to deal with. Ship quick and have nearly everything in stock. They have a nice rubber strain relief boot for different sizes of connectors which is available sometimes in many colors or typically black.

You also can purchase from them the glue filled heatshrink in many sizes which works well as strain relief and waterproofing for weird sized connectors.

Ask for Joel and tell him where you heard of them. Highly recommended.

Hope this helps ..... Steve

The whole damn internet is subsidised by the government. I work
at a government facility if I sign up with a local provider I go
through the same machines and T3 lines I would go through from
work. I use a national provider because I travel so much. I don't
post from work for exactly the reason cited above.

Might I suggest 2 Kits. A MFJ 8400 2 meter receiver, which uses a MC13135, and the FM6 2 Meter FM transmitter by Ramsey. Should give you a good start on design. All you would need to do is figure out a good Phase Lock Loop circuit and you would be done. The MFJ uses a Cap tuned VFO, eeuuuch, can you sat scratchy. Let me know about the PLL stuff, I am still looking for one myself.

Regards

Hi Steve,

I see no one answered you. The design of the inductor is complex.

You would be better off doing it emperically rather than learning a
process you may only use once in your life, unless you *want* to learn
how.

In any event , you need to know the circulating current through the
component and the desired impedance. What is the median impedance
value of the pi-L you are using, by that I mean the output impedawnce
of the pi- section, or input impedance of the L section? What are the
extremes in load impedance, including reactance?

Message-ID: <01bc3c7a$89742c20$ef1810d1@dale>
Source record: 95546

What's the general consensus regarding the use of relays for switching antenna feedlines?

Beyond the power level/handling requirements, are there any particular relays that are recommended more than others for use at different power levels (QRP, 100-200w, legal limit)? Over the years, I have used all kinds of relays with little regard for SWR, losses or power; they all seemed to work pretty well--little, if any, SWR change, no arc'ing problems, etc.. Generally, I use relays inclosed in plastic cases, but otherwise, that's pretty much the limits of my selection process.

What say?

There is practically no phase noise on a DDS. What there is, is spurious outputs. These depend on the DDS chip you're using, the frequency you're on and the "nearness" to the Nyquist frequency, (1/2 the frequency of the clock oscillator). I have measured spurious on the Analog Devices 7008, with a 50 MHz clock at an output frequency of 4 MHz, and found them to be 60-65 dB down from the carrier. This "ain't bad", but it "ain't good" either. It is irresponsible of the various magazines to put out articles on these such as the "Ultimate VFO". They're not the ultimate or anywhere near. And if you're running more than QRP with one, please don't move in next door to me, I'll be over to put a pin in your coax! For a rig like Rick's direct conversion things, you'd be much better served with limited coverage and a VCXO, and it won't cost you >$100 either if you build it. I'd consider the 7008, the minimum DDS configuration, and they run $40 a pop, not counting the shaft encoder and the other goodies required to make it play. You could use it on 160-40, but even 20 meters is getting too close to Nyquist for a good spurious semi-free output.

Why not make your own with 35mm photo film containers and 8 pin octal valve bases (from non-working valves)? Simply drill a hole through the bottom of the film container and remove the spigot from the valve base. Removing the spigot should reveal a hole through which you can pass a metla scre to hold the base to the film container. You'll need about 20-25 turns of thin plastic covered insualted wire for an 80m pi network, and about half that for 40 metres.

to; w1ksz@juno.com (Richard W. Solomon)

Hi Dick,

I am interested in variable capacitors for building
144 MHz antenna tuner for balanced 450 ohm ladder line.

The common circuit calls for
1. 50 pf regular for input
2. 25 pf split stator for output
It would be nice if the two varible sections could
become separate to become in series with the output coil.

I'm not running over 100 watts. In fact only 2.5 now. :-)

Perhaps you would like to trade for something, or cash?

73, Don N6MCE

I have some components for trade, let me know what you are seeking.

I'm in the process of building a receiver for weak signal LF work. I looked at the DDS oscillators and was quite frankly impressed with the human interface side of the thing. You can have selectable step size while tuning, readout on a LCD, etc. The spurious output problem dictated that the use of a clean VFO with a drift correction circuit however. Sure I'll have to build a freq counter for readout on the VFO but that won't be to bad.
You will have to decide what your purpose for the R2/T2 is. If it's pulling signals buried under tons of noise out, you better go with one of the low noise VFO circuits. You can do like I and stabilize it to a hertz or two with a simple circuit also. I don't really know how sensitive a R2/T2 is but I remember something in the article saying that it's not quite up to a good superhet design in that department.
Hope this helps.

Mark

3541. Re: Toroids for Pi-Net

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-03-29 00:00:00 UTC
From: Steve <thebizlk@erols.com>
Message-ID: <333DA286.1319@erols.com>
Source record: 95556

Okay, here goes.

The inductor will be an addition to an already existing amplifier that appears to have been built for the 13.6 ISM band (although I'm not 100 percent sure.) Looking at the tuning cap and the existing inductor, the circuit won't work at amateur frequencies lower than 20 meters. Due to size constraints, I'd like to add a toroid inductor and an appropriate switch to obtain 80 and 40 meter operation (and 160 if I can).

The existing circuit is a straight pi. The input Z would be around 3k. The output Z will be, of course, 50 Ohms. Some amount of reactance will be encountered but nothing worse than maybe a 2:1 SWR on some of my antennas at some frequencies. I'm assuming a tank Q of around 12.

Is this enough info?

If you do calculations, could you send them to me. Yes, I do want to learn, even if it does hurt!

the easiest way to go would be if BOTH repeaters had controllers capable
of link input/output. this way you would put a radio at each site with
a beam type antenna pointing at each other. the radios should be on an
unused simplex frequency in accordance with the accepted bandplan

I have approximately 20 really nice hermetically sealed 8 pole filters.

They are 50 ohms in , 50 ohms out, 2.4KHZ wide with a 10.7 Mhz center frequency. I have used them in several receiver projects with great results. A friensd at Scientific Altanta ran the responce curves for them on a network analyser and they were very nice. A 3.7 Mhz VFO results in a nice 40 meter receiver.

I would like to sell the lot, and am willing to part with them at far below their value.

find attached a schematic that will allow you to "key-up" the radio with
remote PTT button. that's all i can help you with. the shematic works
well in my applications.

Your claim does seem a bit extraordinary, and extraordinary claims require extraordinary evidence.

Certainly there are cases in history where the leading experts dismissed something because it was "impossible". Certain physics professors in 1905 were still writing that the Wright Brothers claim to have made a flying machine was fradulent despite the fact that they had demonstrated their machine in public in front of thousands of people. The Wright Brothers prevailed, because they showed the world that they could actually do it.

More recently, a group in Utah claimed that they could make hydrogen fusion at room temperature in a jar of water. Some scientists dismissed the whole thing at once, "knowing" that it was impossible. Others kept a more open mind and did not dismiss it immediately, but they still quite rightly wanted to see it in action. Unfortunately, none of the cold fusion groups to date have been able to show a working cold fusion cell, and those who claimed that they had had in fact made some error in their measurements.

Sometimes a person like Einstein comes along who really does rewrite the existing laws of physics, and whose work withstands repeated tests over a long period of time, but far far more often the claims of new physics turn out to be mistaken after further examination.

So show me a working demonstration, or explain clearly how your discovery works. Show me enough detail so I can figure out where you made your mistake, let me examine your apparatus in detail, and if I can't find any mistake then, and only then, I might believe that you have uncovered some new

communications principle. Until then I would not advise any investor to put his money behind your discovery, because it does claim to defy well known principles of radio communications which have been around for many years and which I will not abandon easily. Keeping an open mind is one thing, but we still need to see some convincing proof that your claims are correct and that the many experts are wrong.

The repeater system at ve3rpt/ve3tfm and ve3ulr has already set up an
extensive array of repeater linking in the southern ontario area. If
you would like information about it use your search engine and search
for tfmcs. If you have further problems making contact with them send
me an email and i will see what i can do. their system has been
working since the mid 70's.

Hello Matthew / others

I know there are some sample circuits at:

http://www.argonet.co.uk/users/4qd

not too sure whether there is much Amateur TX/RX might be worth a
look see. I know of an SM station maintaining a library of Ham circuits
which are availble using the REQFIL server on the AX-25 network. I will
have a look around on the shack computer and post the gen here if I find
it..

3559. Help: Static kills DX-390!

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-03-30 00:00:00 UTC
From: wmeara@erols.com
Message-ID: <333ee1af.13264442@news.erols.com>
Source record: 95574

My Radio Shack DX-390 has been working fine for several years. Recently, I had it in the laundry room when I was separating recently dried clothing. I pulled apart a shirt and a sheet and I noticed quite a bit of static cling! Next thing I know the nearby DX-390 has lost almost all of its sensitivity. Nothing comes through on the HF bands and only the strongest Broadcast Band stations are audible. All the PLL circuitry and the audio stages seem fine. I suspect the static charge took out the front end transistor. Has anyone heard of this kind of catastrophe before?

Anyway, I want to fix it. I don't have a schematic for the receiver, but I notice that Q1 and Q2 are both discrete components. Q1 is marked 3K152 3 2E:

Any suggestions on how to fix this radio? Static cling never took out one of my old Boatanchors!!!!

I have an unused Millen dial, in the original box with panel layout paper. This dial has never been taken out of the box. I bought it new many years ago. On the box it says:

Millen 10037
No-string Panel Dial
Full vision-Illuminated
Ratio 11/1

I am pretty sure this is the same dial used in the HBR series of home brew receivers shown in old QST and handbooks. I am asking 25 dollars and you pay shipping.

Lightning detectors do exist. Not too long ago I saw a TV science show

about it. Was in US and (I think) France, but I can not remember what

detector was used. Maybe someone else does.

Way back when...i used to use a oscilloscope tube and had one dipole orientated east and west connected to the horizontal deflection plates, and one orientated north and south connected to the vertical plates. With a little experimentation i could tell from what direction the storm/lightning was coming from. All ya need is a scope tube like a 3BP1 or so and the circuit to power it up and a couple of dipoles.

Hello all,
I have a Yaesu FT-2500M for sale.
About 7 months old,low hours,great condition,alpha display,mil-spec.
construction,5-25-50 watt output,31 memories,built in tone
encoder,extended receive,mod has been done for extended transmit.

I have box,packing,bracket,wiring,manual,etc.

Asking $200 and I pay shipping.

Also have an Allmax eprom programmer.

Used 1 time.I paid $650 for it and will negotiate price.

I also have an MFJ 949E tuner for 1.5-30MhZ.

I transmitted once with it.No box or manual but it's in excellent
condition.

Asking $100 or best offer.

Also have an Astatic Night Eagle microphone,never used.I never even put
a plug on the cable.No box,have manual.A little dust but looks
beautiful.

Asking $90.

If interested in anything e-mail me at larry666@gdi.net

73,
Larry Ke4rur

Grant, Grant, Grant,

You, whose opinions I have grown to respect so highly--are you now falling prey to that unique American marketing phenomenon--"charge a lot and your customers will become evangelists"? I can't tell you how many times I've seen this almost subconcious reaction to paying more money for something--it's a knee-jerk response that results in the ongoing self-justification and attempt to convince others of the wisdom of your actions.

Think of the number of Boatanchor enthusiasts outside of the small coterie of 700 that cannot offer their experiences to readers of Jack's For-Pay list. Might there not be many more than 700? Think of the often deep ruts that the party of 700 fall into--interesting to a few, I suspect, but perhaps not to the many.

I value the archived digests of the For-Pay list up on sunsite and am truly glad they are made available, but I hardly view an attempt to provide a (traditionally normal) free equivalent as an attempt to undermine it. I am not alone in my distaste for the tone of the operator of the For-Pay list, and feel that more bandwidth is wasted scolding the elder ops that are probably not as computer literate as we younger types. And I would like to know why it is the only list I'm aware of that DOES cost money, and in fact has posted a 75% increase in only its second year of For-Pay operation. What will it cost next year? $30?

To me, it's hardly the money--it's the attitude. But worse than the attitude of its "owner-operator" are the attitudes of its members when presented with an alternative--what's the name of the psychological state of mind where kidnapped people start to identify with and even like their captors--aside from the Patty Hearst effect--is it the Stockholm Syndrome? Reminds me of that. Yikes, can't we all just get along?

Change--the only thing that is constant.

Your BA friend,

Roger WA3FLE
Norristown, PA

That was very common on some Sony shortwaves, very similar to the
Radio Shack receivers.

>Anyway, I want to fix it. I don't have a schematic for the receiver,
>but I notice that Q1 and Q2 are both discrete components. Q1 is
>marked 3K152 3 2E:
>
>Any suggestions on how to fix this radio? Static cling never took
>out one of my old Boatanchors!!!!

By the Japanese numbering system a 3K152 would be dual gate FET.

Radio Shack is quite good at manuals and spare parts. (The problem is
getting the sales clerks to understand what you want).

One channel is the special order catalog shelf at each store. One
of the sections is repair parts for their equipment. You look up
by catalog number of the original equipment and it gives the order
numbers for various special repair components for that unit. You
then fill out a form and have the clerk enter in the order.

Another channel is Tandy National Parts, a 1-800 phone operation.
They have the same sort of information by model and will take
phone credit card orders. I don't have the number handy, but I
got it by calling 800 THE-SHACK and getting it from the operator
there.

Third, the radio is probably a private labeled version of a Sangean
shortwave. Service information for their similar model should cover
yours.

Finally, there are a number of distributors that serve the electronics
repair market and one of the things they do is carry Japanese
semiconductors. Outfits like MCM, Dalbani, Premium Parts. Rather than
type in all their addresses, try the sci.electronics.repair FAQ at the
web address http://www.paranoia.com/~filipg .

>Why won't it work, if you have enough signal strength?

>The Si diode only takes about 2x the voltage to conduct as the >Ge diode...

>Am I missing something?
And that 2x voltage (about 700 Millivolts) would require a lot of
RF energy to cause detection. Silicon diodes aren't very good
as low-level RF detectors, sorry.

>(Not that 1N34A's are that hard to get)
There in every radio and TV made. Take a look around any
bone-pile of gear and you should be able to come up with one.

An alternative would be a hot-carrier diode used in high
performance balanced mixer applications. These diodes
conduct at about 400mv. HP use to make a complete line
of these devices, so there may be some data sheets around.
The part numbers escape me know.

cheers,

Greetings,

For the party interested in repeater linking. The southeast Iowa technical
society has quite a network of linked repeaters, using a hub repeater
approach on 70 cm.
The system contains two meter and 1.25 meter machines. For more
information on that system point your browser to

What would I need to do besides shield the card and use an outside antenna? Or are you saying the shielding itself would create problems? I'd think the problem should be solvable because you can already buy a highly-rated SWR on a PC card, the WinRadio.

3585. Static Cling and DX-390

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-03-31 00:00:00 UTC
From: wmeara@erols.com
Message-ID: <333fdbb4.914061@news.erols.com>
Source record: 95407

Somehow most of this message got dumped in the bit bucket: Let me try again:

Last week I was happily listeining to my Radio Shack DX-390 receiver while simultaneously performing some routine laundry tasks (sorting recently dried clothes). I noticed that while separating a couple of wool shirts, lots of static elecricity was unleashed. The receiver crackled appropriately, but I dodn't think much of it... until I later noticed that the radio's front end appears to have died in the process! Sensistivity WAY down on all bands. Only the strongest Broadcast stations get through.

My guess is that the electrostatic charge took out the front end transistors. RS didn't provide a scematic, but I see Q1 is marked 3K152 32E:

Any tips on fixing this thing? Anyone heard of similar static problems? This never happened with my Hammarlund HQ-100!!!!!!

Thanks, 73 Bill N2CQR

Actually a couple of three foot diameter 50-turn loop gap antennas with
a small vertical antenna to provide a blanking signal to eliminate the
directional ambiguity (i.e. is the received signal to the north or south
of the east-west loop) will work quite well. Direction can be read from
the CRT face and relative distance can be estimated by signal strength
[sort of :)]. There is a site however, http://www.boltek.com that has
a more elegant solution. His system will interface to your PC, record
and display realtime strikes.

I'd be curious to know if there are any other methods that anyone has
tried (that don't require a line item in the national budget or half the
continent for an antenna farm !).

Regards,
Rolf

It also has changed somewhat. Back when people bought an HW-8, followed the step-by-step instructions, poked the components into the holes, and soldered them, they would tell you they were using a "Heath HW-8". Apparently, this would now be a "homebrew" rig.

Admittedly, this is slightly more complex than taking a rig out of a box and turning on a switch, and I'm surely in favor of kit building. But is it now "homebrew"?

NO NO NO!!! Stay away from that FM-6. It's a basic 12MHz osc/multiplier
design with no filtering at all. It does however make a great comb generator,
putting out spurs every 12MHz up and down the band. Like with ANY Ramsey
kit, do not put it on the air without checking it first with a spectrum
analyzer and doing all the required mods to make it ligal.

I thought the P3D antenna gain and power output was high enough to allow the use of omni antennas on the ground. Is this not true?

3593. Need help with YIG Oscillator connections

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-03-31 00:00:00 UTC
From: Perry Kottke <pkottke@execpc.com>
Message-ID: <33401033.4BE1@execpc.com>
Source record: 95415

I have a Watkins-Johnson YIG Oscillator that covers 2.16-4.16 GHz.
It is in a cubic package about 3.5 cm on a side. There is an SMA
connector on one side and 8 feedthrough terminals on another. I
realize 2 are for a heater, 2 more for the magnetic tuning coil,
2 appear to be for a thermister, probably for temperature
control/feedback for the heater. That leaves 2 more terminals for
supply, neither of which are at ground potential as referenced by the
SMA shell. Does any body know what to power this thing with, and
how is the heater typically used, ie over what temperature range.
Any technical info is appreciated as I have no experience
with these devices as of yet.
Thanks - Brad

Hello Simon OM,

If you want to control the transceiver with a computer, build the transceiver OUTSIDE the computer in its own box, and simply connect via serial or parallel interface to the PC. The data rate for control is very slow anyway (almost static lines). The sound card can be easily connected externally with audio cables. Placing a good receiver inside a PC is surely the hard way to accompish the above. It is a terrible environment of broad-band noise. Also, the transmitter may very well cause crashes in the computer due to RF getting on address, data, and control lines unless you have very thorough shielding of your XMTR. You will probably need to put the entire transceiver in a box INSIDE on the PC card anyway, so why not keep it outside in the first place? In any

event, you will want to prototype the rig outside on the bench to begin with, due to accessibility.

>
> >W4ZCB

Hello W4ZCB OM,

A DDS can generate spurious outputs close to the DESIRED frequency.
This means you cannot use a simple BPF to clean it up. The further out
from the desired signal the frequencies are then the easier to filter
out, of course. I would not worry about spurs that are 50-60 dB down
for tranmitting, myself. See recent issues of Communications Quarterly
and Analog Devices data sheets for explanations of DDS spurious outputs.

there's no real modification to increase the power BESIDE cranking up
the pots clearly marked in the owners manual. 15 watts on 2m is about
it and 125 watts on the hf portion. this exceeds the design specs so my
advise is an add-on power amp to provide the required power.

3597. R2 RECEIVER

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-03-31 00:00:00 UTC
From: Don W6JL <donh@vcd.hp.com>
Message-ID: <33401F37.3D6A@vcd.hp.com>
Source record: 95419

Hello Homebrewers,

I have recently completed a version of the R2 receiver. I am very impressed with its performance. Using hand-matched (to 1%) components in each channel of the audio diplexers and phase shifters, I am getting 50 dB of opposite sideband supression over the audio bandpass of 300-3000 Hz. I am using a homebrew Wilkinson power splitter and pi-network for the RF LO phasing (per the QST article). I can hear 1 uV RMS in a 3 KHz audio bandwidth with no RF preamp and a passive double-tuned critically-coupled preselector. Noise figure is around 12 dB. This makes the receiver entirely sensitive enough for 40M work as-is. The audio is the best sounding I have ever heard from any receiver. I have designed a 500 Hz 7-pole ellyptic LPF for CW and FSK use.

I too am working on a DDS VFO for my R2. I want to provide wideband quadrature (I and Q) outputs, and am thinking of using two AD9830 DDS chips for that, one at 0 deg phase, and the other at 90 degrees, running off the same clock. I run 2V p-p into the power splitter of my RF phase shifter, so I will use wideband feedback type (2N5109) amplifiers at the output of each AD9830.

We are living in a great time for homebrewing, guys. Never has it been easier to make excellent performing receivers and transmitters with readily available, relatively low cost parts. Sure is much easier than the old days (I remember them well) of chassis punching and terminal strip wiring!

I used a blank PC board from Kanga for the R2.

73,

Don, W6JL

The Sony 2001D had this problem sometimes, I believe, when external
antennas were attached. Static could blow the front-end FET. Sony
subsequently modified it. Mine's OK, but I only use it with the
telescopic antenna, anyway.

Karl Skoupy wrote:
>
> Hello
> Is there a mod to increase the power for the IC-706 ?
>

Hi Karl. I haven't heard of one & doubt that one would be practical/beneficial. With the size of the heat sink on the 706, perhaps a small increase in power (20-30 watts) could be tolerated, given reduced duty cycle operation, but such a small increase (approx 1 db) wouldn't make any difference on the air. If you wanted to go wild with extra cooling and final (maybe driver) replacement, you could probably coax 200 watts from the thing before the other circuits went into meltdown. Is 3 db (half an s-unit) really worth it?

If you need more signal, make sure the antenna you are using is as optimized as it can be, then (and only then) think about an external power amp (and the huge current it will require!).

Good luck!

Hi Roy,

I would call it a KIT. However, I do not believe you have to design the
rig in order for it to be homebrew. Perhaps it starts being homebrew
when you layout or make the circuit board and housing- a few mods would
certainly qualify. Call it what you want- it should be encouraged.

As an aside- I never met a more genuine group of courteous and
knowledgeable (sp?) hams than at the Dayton QRP get togethers- old time
ham radio.

I get my big magnets from old speakers. They aren't always available, but I've found a fair share of old speakers in the garbage (and I don't go digging through the garbage, only sometimes notice the speakers on top).

The last one I found was behind a club, and the speaker is massive. YOu don't want to mess with it.

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
April 20th, 1997
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >1000 cars!

Buyers admission is $4 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $10.00-each at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Seperate lines will form prior to gate opening
for prepaid and nonprepaid vendors

A discount sellers SEASON PASS is available for
$50 per space if purchased by April 20th.

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 146.52 and W1XM/R-449.725/444.725 (PL 114.8/2A).

Just to add to the above re circuits, I found the following in

comp.archives.ms-windows.announce

I have uploaded to Simtel.Net:

http://www.simtel.net/pub/simtelnet/win3/elec/lokon21.zip
ftp://ftp.simtel.net/pub/simtelnet/win3/elec/lokon21.zip 756193 bytes

lokon21.zip Construction & simulation of digital circuits

LoKon will help you with the construction and simulation of digital circuits. It is the most comprehensive product of its type and is a must
have program if you are involved with or interested in digital circuitry.

Feature include context sensitive help (600 KByte) and menus. More than 100 elements (gates, flipflops ...), oscillator, ROM/RAM, PLA, and an oscilloscope. Comfortable creation of own elements.

Includes comprehensive self contained manual and has been tested on Windows95 and OS/2.

The zip file contains the English and German version.

New in LoKon V2.1:
- TTL elements

New in LoKon V2.0:
- Undo/Redo
- macro element for cascading circuits

Hello everyone!!

Please take the time to have a look at my new Web Site. It's only a first attempt so don't be too critical. At present it only has a few bits active but each week I intend to extend it so BOOKMARK it and call back each week.

It will hold a list of links I have found of interest both amateur and commercial, plus the EDDYSTONE USER GROUP. In addition there will be items for sale including BoatAnchors, previously enjoyed classic books on radio, old magazines and much more.

The address is http://www.plasma.co.uk/simon/ so do have a look and I hope you find it useful. Any constructive comments would be most welcome.

Regards

Simon

Separate the reciever from the control.

It takes a lot of engineering to put a sensitive reciever inside
a 30 to 100 watt broadband noise source.

What power levels are you talking about? The only thing that
would limit your design would be the power level and the
size of the core you are using. At low power levels T60 & T80
size cores can be used, but if you are talking about higher
power levels you would need to go with a larger size core (or
two cores stacked) to avoid saturation of the cores.

Lets hear from others as I am no engineer!

Down East Microwave has avaliable in kit or assembled a
RF attenuator switch system so you can turn the power down
on the (power or mic gain) TS440 and operate the transverter
from the antenna connector. It can be used with any transceiver
with up to 40W output, check downeast's homepage out at
downeastmicrowave.com

Yes, there are a number of suppliers listed in my file PARTSUPP.TXT
which is available at:

http://www.mnsinc.com/bry/hamfiles.htm

Click on PARTS to get a copy of the list. Then do a search or Find for
the words "New York" or "NY" and you should find a number of neat
places.

Yes - ARRL has a program called HAMCALC that will do this for you.

I think it is available at their web site

http://www.arrl.org

With the transceiver switched off, press and hold the MHz button near the
upper left while switching the transceiver on.

Release the MHz button and press the F/W button. Then, within five
seconds, turn the selector knob to set the desired display brightness.

Wait five seconds, or press F/W again, to return the control functions to
normal operation...

I've seen a couple mentions here recently of a "for profit" BA list.

Apparently, there's a few people with either a mistaken understanding of, or a mistaken assumption about, the BA list.

I don't even own a BA radio, but I like old test equipment, so I subscribed. I'm on several professional mail-reflectors, for cad/cam software, cnc machine tools etc., and I have to say that the BA list is the smoothest running mail reflector I've ever seen. And I love the strong moderation. That's the best part. It's always peaceful and courteous and productive on BA. Any baloney gets squelched fast.

I've done some research into website setup for work, so I know what telcom costs are like. I've also paid attention to the development of BA. The listowners there have lost over $10,000 in the past few years. That is to say, they dug into their own pockets to keep it going and going well. This is a fact.

The subscription fee, a whopping $1.50/month, isn't nearly enough to cover the costs of running an active mail-reflector with close to 1,000 serious members. Think "T1 line costs", think "$1,000+ software packages and updates", think "Unix servers" etc., etc.. It costs real money to process 50,000 mail transactions a month -smoothly and without errors-.

And those who've never managed a busy mail-reflector can't even imagine the hours of admin work involved, not to mention the incredible abuse that rude people pile upon you. It is truly shocking how childishly grown men can act. Of course, anybody who reads rec.radio.swamp experiences this on a daily basis. Remember, the BA listowners aren't getting paid dime one. They do it because they truly love BA's.

Anyway, a discussion of cost vs. no-cost might make some sense, but let's drop the 'for-profit' terminology regarding the BA list, 'cause that just doesn't make any sense at all.

>Thanks - Brad
>

Hopefully you have the model number of the oscillator. If so, post it; someone may have the exact specs. Without that theres no way to say for sure what voltages are needed. Usually 2 pins are for the heater -- probably 28V at 1 to 2 amps max. Two pins are for tuning coil - needs current driver. Two pins usually are a finer control FM tuning coil. DC for circuits depends on the YIG design. Some WJ specs I looked at use +15 and -5 V, others use +15/+5. Many YIG oscs need adjustment of bias voltages for best operation across the tuning range.

As I said, if you post the model you might get a more exact answer. You may blow the thing if you apply wrong voltages to the circuits.

good luck,
Rex

Thank you, Richard! It's really tragic that some have not looked into how well the ORIGINAL BA List works. It's free to all comers for a mimimum of 4-weeks inspection.

What's more tragic is that the list owner at tempe.gov chose to plagerize the name of BoatAnchors thereby impugning the BA Newsgroup as well. We know this latter was a much careful and laborious construct to offer a free avenue for those who preferred not to pay a trivial membership fee.

No one even in the commercial would attempt such a back-stabbing maneuver. Ethics are important to MOST folks.

What's even sadder than the name rip-off is that the server is run by public funds!

I subscribed to see what was going on and so far have read nothing different than much of the stuff on rec.radio.amateur.boatanchors. There is a similar list called otrig-l that is free for anyone to use. I fail to understand any logical reason to set up another list. The digests are freely available to anyone who knows how to get them so you don't have to miss any of the action on the real list. That wisdom and information costs you zip! However if you wish to participate you gotta join the club!

Those whining about the annual fee which is now $20.00 (but some of us paid early and saved $8.00) should consider themselves fortunate to have access to the digests which, somewhat like a repeater, is NOT a God-given right.

I guess there will always be whiners and complainers so maybe it might be a good thing to have a freebie list just for them. They can play around in the sandbox kindergarten level while the rest of us attend Real Radio University.

Interesting to note: There has not been a WORD of this on The List!

Dan, he may very well be able to do just what he says. What he didn't say is how much Signal to Noise ratio he'll need to get it to work!

You can phase modulate a signal to such a small degree that the carrier barely wiggles. And you can use that modulation index to put all kinds of bandwidth on the air. The problem is that unless you have a very substantial SNR, this system will sound inferior to a wider signal. In a way, this is the opposite of spread spectrum. Use more power and less bandwidth instead of less power and more bandwidth.

The bottom line, however, is that basic rules of information theory still apply. TANSTAAFL.

I have never worked an AMSAT satellite because the gear required costs
too much. I work only RS-10, RS-12, and RS-15. When AMSAT puts up
a bird I can use, I won't be cheap.

Do you have any idea how I can contribute to the Russian Amateur
Satellite Program?

Michael-

The elitism espoused, justified by the technical competency found on the list and condemned by ad-nauseum discussions of 'radio wax' and 'enviro-political testimonials', can only server to intimidate potential participants of the one-true-list without whom there would be no list.

The implied threat, "no god given right...." (to the digests) fosters no good feelings toward contributing, on my part, and can only serve as additional discouragement to potential participants.

Analysis of your post and consideration of the above leads me to only one conclusion. You must be one of the renegades. This disinformative diatribe has to be a well disguised from me, perhaps clear to my intellectual superiors, attempt to sabotage the one-true-list.

Thermionics forever!

The best relay would be a coaxial type that maintains the 50 ohm impedance thru it. An ordinary open relay would introduce an inch or so of improper impedance. This is not significant till you get to vhf or higher where this represents a significant part of a wavelength. Even there some commercial vhf rigs use open relays. At high power levels look for large contact surface and good insulation. An external case is probably not significant usless you are worried about dust getting on the contacts. 73 Jim N0TN

>I thought the P3D antenna gain and power output was high enough to
>allow the use of omni antennas on the ground. Is this not true?

Wow, been digging in the archives. eh? P3D has a 10x larger power
budget than AO10 or AO13, but I think you'd be hard pressed to work
it using omni antennas when it is at apogee. I understand that it
is planned to be active on more than one mode at once, so the larger
power budget will be shared across more than one transponder at a
time. And while greater output power will make it somewhat easier
to hear, extra power supply at the satellite doesn't make it hear
you any better.

It is supposed to be 3-axis stablized, so squint angles shouldn't
be as much of a problem as they are for AO10, and were for AO13,
but I don't think that will be sufficient to allow you to work
it without a steerable gain antenna at your station. (At perigee,
of course, it should be possible to work it with an omni, but it
won't dwell at perigee long, and coverage will be much less than
when it is at apogee and a whole hemisphere will be in its footprint.)

It shouldn't take quite as elaborate an antenna system to work
P3D as it does to work AO10 (or did to work AO13). Fairly compact
beams should suffice. You shouldn't need anything like the 22 el
2m and 40 el 70cm long boom antennas I'm using for AO10. An 8 el 2m
and a 16 el 70cm antenna should do nicely (that's for CP, halve the
number of elements for linear polarization). That's a boom length
on the order of 6 feet. If you're running a good amp and have a
good mast mounted preamp, you might get away with even smaller
antennas, say a nested quad backed by a reflector screen (but
with decent antennas you shouldn't need to run an amp at all).

You shouldn't have any trouble setting up a workable antenna system
on a patio or balcony. You can cheaply build the antennas needed.
And as I noted in my original post, you can hand steer the antennas
as long as you aren't trying to work perigee passes. The molynia orbit
has a very long dwell at apogee so you don't have to reposition very
often.

The real digital action may be up at S band, and the needed antenna
for that can be quite small. A 1 to 1.5 meter dish should be plenty,
and that's easily handled on a tripod. You might even be able to
dual feed it and use it at L band as well. If not, a modest loop
yagi will do for L band. (I'll be using my 12 foot dish, because
I already have it, but I'm going to have to throttle power *way*
back to avoid being too strong at the satellite.)

P3D is going to be much easier to work than our previous molynia
orbit birds, but don't expect to work it at apogee with a microsat
class station. You'll want a receive antenna with a narrow enough
beamwidth to keep the warm Earth from affecting system noise
temperature (otherwise a low noise preamp will do you no good),
and you'll want a transmit antenna with enough gain to avoid having
to run an external amp. With my current setup, I expect to be using
less than 2-10 watts uplink power for mode U/V (the higher power may
be needed to burn through the treeline for near horizon passes). With
lesser antennas, you may need 25-45 watts uplink power.

The receive setup is really the key, however, as it always is with
satellites. You simply *must* have enough directivity to let the
antenna look at the cold sky. Otherwise system noise temperature
will be limited by the warm Earth, and you won't be able to compensate
by adding more preamplification. An antenna with a 3 db beamwidth of
22 degrees, and a good F/B ratio, should suffice for high passes.
A narrower beam will be needed for near horizon passes.

3644. Who can save from NOISE?

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-01 00:00:00 UTC
From: bv3fg@alumni.nctu.edu.tw
Message-ID: <5hra2d$k2k@netnews.nctu.edu.tw>
Source record: 95459

I have been suffering from heavy local QRM for 2 years.
The noise sounds like sparking 60 time per minute when freq. is above
5 MHz. On 14 MHz, the strength of the moise is listed below:

PreAmp ON / NB OFF : 9 S-unit
PreAmp ON / NB ON : 6 S-unit
PreAmp OFF / NB OFF : 6 S-unit
PreAmp OFF / NB ON : 3 S-unit

The noise is still very strong (about 4 S-unit) on 50 MHz with
PreAmp ON and NB OFF. So I cannot pick up any weak signal and I must
struggle against the noise for copying the signal so-called 55.

I have made sure that:
1.The noise is ont caused from any equipment in my house and
neighborhood.
2.Ground system (both DC and RF) work well.
3.The so-called low noise receiving antennas don't eliminate the noise
in my situation. They reduce signal and noise at the same time, but
the S/N is still poor.
4.The noise disappears when the whole city loses electricity power.

Because I live very near (about 400m) a large electricity power
transfer station which transfers electricity from about 300KV to lower
voltage, I guess that the noise is generated from this station.

My questions are:
1.Is waht I guess correct?
2.Is AF DSP able to eliminate this kind of noise?
3.Is it possible to kick the noise away before the noise gets into my
receiver?

Please save me from noise!!!

Personally, I can't financially support ANY organization that insists
on using inferior product. I am speaking about the Ariane 5 launch
vehicle. The first one blew up, and the others that had space on
the second launch pulled-out. One would think that Amsat would have
learned over the years that the ESA does not have the world's best
reliability for launch vehicles (anybody remember the early Oscars?
The ones that were lost because the launch vehicle - Ariane - went
into submarine mode?). I know where of I speak, having worked in
the satellite business (RCA and it's successors) for the last 13+
years. When they see the light and use another launch vehicle, THEN
I'll support them (Amsat).

Traditionally, there has always been a 10dB discrepancy between
"AMSAT-promised minimum ERP" and realistic minimum ERP. This, of course,
mostly was because of the AGC action caused by alligator stations,
and on P3D the situation might be better because of the countermeasures.

Of course, directional antennas are always better because they help to
reduce noise as well. You can compensate the gain you get from the
antennas by using less output power.

DDS is a very bad choice for a DC receiver.

I've tried to use several including the discrete DDS using 74AC283's and DAC, to a more high-tech one the AD7008.

Both produce a sound resembling someone playing a xylophone at random as you are tuning. Generally, only strong stations can be heard and the weak ones according to Murphy's law are buried under spurs.

The only way to get rid of the spurs is to use a PLL to clean it up, or use the DDS as the reference for a PLL, like the Rohdes hybrid DDS/PLL ckt. I have built one and it is very clean.

I've also tried to use DDS as VFO for my Drake R4-C. Same problems as in the DC receiver.

Good luck,

Rob.

This is a repeat of my attempt to locate software that will run under WIN3.11. Im looking to input various notes, schematic diagrams from years of collecting onto my computer.

Until now, all that I have seen is s/w that runs under WIN95 and expensive stuff as well. I dont need the functionality of PSPICE/SPICE. Just something to enter schematic/wiring info and get printout at later time.

I think there must be some choice software available that will allow ham radio operators to input schematic diagrams and wiring diagrams into the computer software and then later be able to get screen viewing as well as dot matrix printout.

Please advise.

Both produce a sound resembling someone playing a xylophone at
random as
you are tuning. Generally, only strong stations can be heard and
the weak
ones according to Murphy's law are buried under spurs.

Are you sure the problem wasn't just that the receiver was picking up the digital byproducts through the power supply or the antenna? Making clocked digital circuits and low level analog circuits coexist peacefully is like putting cats and dogs together in the same house.....you need to keep them well isolated from each other. It can be done with a little care though. Chances are that the problem was not with the spectral purity of the DDS output, but something else related to the implementation.

If you need only small schematics got to http://ivex.com/ and get their
free software. It is limited to 100 pins but works well and the have a
companion PCB layout software I have but haven't tried yet...

An obvious question is: Have you talked with the power company about correcting the situation. Sounds like there is a faulty connector or ground system at the substation. I do not know if that is an option in your country or not, but it is worth a try. Good luck.

I had a similar problem with the bias zener in the Heath SB230 (single
8873 conduction-cooled "bottle"). That zener is 8.4 v at 50 watts. I
gave up easily and connected 11 forward-biased 1N4007 rectifier diodes.
I could have used the 1N4001 diodes, but I had a bunch of 4007's. It
works better than the original 50-watt zener. You need roughly 34
diodes for 24 volts, but they are cheap: <$0.10 each. Its better than
"retiring" an otherwise good amplifier!

>on. I'm looking for info on recommneded wire size (for legal limit)
type
>and size of the ferrite toroid and any other pertinent design info.

I built a legal limit linear amp several years ago using a toroidal pi net coil. I used a 4" toriod form of type 2 powered iron material and wound the coil with bare solid #12 wire stripped out of Romex house wiring cable. The wire was sheathed in teflon tubing. The coil worked fine. It was wound for 160 meters with taps for 80,40 and 20. It was extremely compact and worked great. The power tube was a 4-1000 operated grounded grid at 4800 volts on the plate. my Icom 751s max output limited the power output to approximately 2300 watts and I never experienced coil problems. Both of the caps were Vacuum variables, the input was 500pf and the output one 2700pf.

>Satellite Program?

Fair enough. But it's interesting to note that under your logic the only satellite project I should support is SAREX/MIREX, and the only ham radio band I should be interested in keeping as a ham radio band is the 2 meter band. Why should I care about 70 cm, 10 meters, or any other band I'm not on right now?

I don't think you're correct with your comments that AMSAT-NA doesn't support Mode K and A satellites. There's an excellent book available from your local Martha on how to get started on the Russian satellites. And it continues to sell well, indicating that there is interest in those birds.

The keplerian elements for the RS birds are distributed each week by AMSAT-NA, not to mention WWW resources, AMSAT-BB, and other online resources.

If you want to contribute to the Russian amateur satellites then I'm certain we can find the appropriate contact for you. Or a much closer source to home, SEDSAT, under construction at the University of Alabama Huntsville, will have a Mode A transponder. I'm certain they'd appreciate your financial support too.

Phase 3-D may not fulfill every ham operator's dream of a perfect satellite, but it will increase the capabilities of future amateur satellites, which - in the long run - will benefit all of us.

I would like to try to make a couple of Kilovac Vacuum tube relays

into a QSK circuit for my SB-230 Amp.

I would like to use TEN-TEC concept of two control wires from

tranceiver to sense hot switching.

I have read Measure's conversion of 922 and sb220 and Don't have

a clue on use of two control wire system.

I looked a TEN-TEC TITAN schmematic and was overwhelmed by complexity.

ANY HELPFUL HINTS TO GET ME GOING IN CORRECT DIRECTION?

Thanks for possible interest in helping.

Hi Rob, OM,

I am surprised that you were unable to use a DDS source for either the
R2 or as Drake R4-C L.O. Are you sure you had the DDS circuit well
isolated from the mixer you were driving? I am assuming you had the
R4-C well separated from the DDS, no commong power supplies that were
not well decoupled, DDS output fed via coax, etc. I am building a DDS
for my recently completed R2 receiver here. From looking at the
spectral output of the DDS, I cannot see how it should result in the
symptoms you describe, but I could be wrong, as I have not actually
tried it yet. Were your problems the result of close-in spurs or
wideband ones? The specs on the AD7008 show spurs >50 dB down, if the
output frequency is < 1/3 of Fclock (1/3 of 50 MHz). Also, there have
been other builders (QST article on the "digibrain" VFO), who have had
no problems using them as an LO source for a receiver, such as the
Kenwood TS820.
I am sincerely interested in understanding your bad experience in
using a DDS chip as an LO in the R2.

Hi Jack OM,

You didn't say why you wanted QSK. Is it for true QSK CW operation, or for AMTOR/PACTOR operation? I am not familiar with the SB-230, but I have been running my SB-220 for several years with stock t/r switching on TOR, and it works fine, driven by TS820. Both rigs use relay switching, of course. I have measured the t/r switching time on the SB-220 and it switches from r to t in < 9 milliseconds, plenty fast enough for TOR. It runs QSK on CW OK at 35 wpm also. Yes, you can sure hear the relays clacking, but otherwise, no sweat. Have you actually tried using your SB-230 as-is?

Well gee, Jack, if you're willing to pay the difference in launch costs, AMSAT will be happy to use a different launch supplier. But realize that ESA has only had one launch failure with an AMSAT satellite on board, that was P3A, and our ride was *free* on that one because it was a developmental flight. ESA has given amateurs a free (or very reduced cost) ride up until now, as a piggyback payload, and they're only charging $100,000 for the P3D solo launch to GTO. If you know of another launch supplier who'll give us a ride to GTO for $90 a pound, lets hear about it.

The Chinese Long March (which doesn't have a sterling success record) costs 10x as much. Atlas II is even more (and has had failures too). Titan holds the all time record for longest launch delay, 1000 days sitting on the pad before it was ready to go, and Titans have blown up too, and cost even more than an Atlas II launch. And Shuttle is over $20,000 a pound, can't even reach GTO, and has had a spectacular failure of its own. The Russians recently had a blown launch too. Now Proton is about the most reliable launcher in the world, but guess what a GTO flight costs using it? It's quite a bit more than a Long March.

ESA gives amateurs a very cheap ride (way below their cost). The tradeoff for that has been some launch delays, and one launch failure, because we get all the new developmental launches at that price. That's a good tradeoff. We couldn't afford to launch on Atlas, or Titan, or even Proton.

Huh? You can work the microsats with a dualbander, even in some cases
a HT dualbander. If you don't have either of those, a $50 80 watt GE
Exec II or 110 watt Mastr II can make a dandy UHF uplink transmitter.
Use the temperature compensation input of the Icom for doppler tracking
and/or VXO. You've already got the 2m gear apparently if you're working
the mode A birds. Or you can certainly use one of the converter circuits
in the various Handbooks to translate receive down to the HF receiver
you've got to have to work mode A. Antennas are merely a matter of a
wooden 2x2 boom and some aluminum clothesline wire for elements.

If you can't get on the microsats or mode B birds for under $100, you
aren't trying.

3673. Wanted: technical help for micro-radio station

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-02 00:00:00 UTC
From: Mike Dash <dash@primus.com>
Message-ID: <3342EC24.69E9@primus.com>

Cross-posted to: alt.radio.pirate,rec.radio.amateur.misc,rec.radio.shortwave,sci.electronics.repair,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.shortwave

We are looking for an RF engineer to help us start a micro-radio FM station in Seattle. The station will cover a range of things including news, music and spoken word. We have a motivated, energetic group of people. We have a fair amount of equipment. But we don't have a working transmitter, and that's where you come in.

So far we have two transmitters on hand. But neither one is putting out clean signals, so we're up against a wall. We need help from someone who knows RF design and troubleshooting. Current FM broadcasting technical practice is a big plus. If you have access to test equipment, that would help too. Our technical expertise is actually quite good and we've gotten pretty far ourselves -- now we just need your help to get us over the top.

If you think you can help, please contact cameron at 206-729-8409 or email slr@scn.org.

Does anyone have the computer interface for this weather station. In the manuals there are some instructions to connect to the microprocessor to gather data. It appears to be a parallel interface but I have been unable to locate any information on this connection. Also is this the same interface as the ID5001 weather station.

Thank You

If you barely phase modulate, you simply have NBFM or NBPM, which
as we all know, occupy the same bandwidth as AM, no matter how
small the deviation.

Regarding SNR, if you assume 90 dB. SNR, the Shannon limit is
something like 3,000 bits per second.

Usually when one sees these claims, the validity of the claim
hinges on accepting some non-standard definition of "bandwidth".
For example, the narrow FM scheme "works" if you define bandwidth
as the band in which 99% of the energy lies (or pick any other
%). You can always satisfy this criterion if you use narrow
enough deviation, and you have the SNR to get away with it.
Other claims of this nature depend on using spread spectrum
techniques to "borrow" spectrum from some other service, in
which case the inventor says that spectrum doesn't "count".

So I would encourage the inventor to rephrase his claim in
rigorous language, defining what he means by occupied bandwidth,
what post-demoduation SNR and bandwidth constitutes listenable
music, and what assumptions he is making about the "channel"
over which this communication is taking place. For all I
know, he is going to send the "music" as MIDI data to be
reconstructed at the other end. I wouldn't be surprised if

you could connect a piano roll to a player piano over a link
that would fit into 100 Hz. bandwidth. Does this constitute
"sending music over a 100 Hz. BW"?

After a while, one starts to approach these claims like one
evaluates a "bar bet", where semantics are everything. Also,
regarding the Shannon limit, if you had actually read and
understood Shannon's paper, "The Mathematical Theory of Communication"
you might be less inclined to just blow it off, as
you seem to be doing. It really is an airtight proof.

If you want to keep the materials under the category of 'stuff around
the house', you can try using the razor blade and needle technique
of providing detection.

This is the infamous 'GI foxhole radio' that soldiers used to
put together to detect AM during the WWII.

I dont have the specifics, but articles on these are relatively
common, I have seen lots over the years. Everything is basically
the same as a crystal radio except that the razor and pin are
used instead of the galena or diode.

Good luck!

Actually, the one you speak of is the third BA list. The "original" one was at gnu.mit.edu.

> What's more tragic is that the list owner at tempe.gov chose to
>plagerize the name of BoatAnchors thereby impugning the BA Newsgroup as
>well.

"Boatanchors" is a generic term that dates back to at least the 50s. Hams and ham magazines have used it now for decades. That was the basis of our arguments for the creation of the BA *newsgroup* name, when those who fought against such a name said it's not widely recognized.

>We know this latter was a much careful and laborious contruct to offer
>a free avenue for those who preferred not to pay a trivial membership
>fee.

Think of it this way: With two BA lists and a NG (and now Collins and Heath lists, too) a greater number of hams who are interested in equip-ment of past decades can be reached.

> No one even in the commercial would attempt such a back-stabbing
>maneuver. Ethics are important to MOST folks.

What do you feel was done that is unethical? Choice of name? The name is generic. Free venue? It gives those who've left over the past 12 months another forum to participate in, and brought in new folks who had never sub'd to the paid list (the latter equates to more of the older equipment (and tubes) being saved rather than being dumped into landfills!).

3683. Design advice sought for active antenna from radio engineers/hams

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-03 00:00:00 UTC
From: archer@netgate.net
Message-ID: <334368ce.95973964@nntp.netgate.net>
Source record: 95350
Cross-posted to: rec.radio.shortwave,rec.radio.amateur.homebrew

I've designed a really quiet three-stage GaAsFET pre-amp for an active antenna, and it works very nicely with a 6" whip on the West Coast as long as I shut down both of my PCs and all fans/motors. (Those little MRF966 GaAsFET puppies are almost $5 each, but they sure bring the signal up without adding noise...) I haven't measured the gain of the

thing because I don't have the equipment, but it nicely hot. Nonetheless, it's aggravating to be plagued with RFI.

I'm told that this sort of interference is short-range, and that the best solution is to put the active antenna outside and up above the noise sources. Okay, this sounds like good advice, but it brings up a lot of questions:

1. Should I put the amplifier up with the antenna? If I do this it might be hard to control the gain remotely, and presents some weatherproofing (static-proofing?) difficulties, but then I won't have to worry about losing signal in the coax lead-in. Also, I don't have to worry about super-shielding the amp if it's away from the local noise?

2. I need some sort of an AM filter to keep from overloading the preamp. Should that go in front of the first stage, or after a stage or two, or should it be at the receiver (I'm worried maybe the coax will pick the AM back up even if I'm very careful to filter it at the antenna or antenna amplifier, or am I being paranoid?)

3. Would a hybrid approach be worthwhile? I'm thinking of putting maybe 1 or 2 stages of fixed-gain amplifiers at the antenna (enough to compensate for the coax lost worst-case and then some but not enough to ever overload -- because it's irritating to have to climb on the roof to switch on an attenuator -- hehe) and then have a "box" at the receiver end with the remaining stage(s) with adjustable gain and filter.

Design goal is top performance without being overly difficult to build, so that others can play with the design and not spend over (say) $200 and a weekend of assembly for everything. So I want to avoid fancy relay/remote gain control/microprocessor-control/remote tuning assemblies.

I'm willing to share the schematics, experience gained, etc. with the group on the theory (and I may
be completely wrong about this) that a no-compromise design will exceed almost anything you can buy store-bought, or at least

anything store-bought that I can afford! ;)

Any radio engineers out there with advice on this?

Why try to figure out how to use a two control wire system on a one control wire system that operates in under 2mS? If something works, why fix it? A two millisecond amplifier is faster than any radio currently on the market.

Why use two HC1 vacuum relays when you need only one plus a Matsushita RF reed relay that costs $10, makes or breaks in under one millisecond, and is acoustically quite a bit quieter?

It is not necesaary to transmit in real time. If the music is digitized
and sent as a very slow data stream using MSK or QAM, etc, the bandwidth
and the SNR can be anything we like.

But it may take awhile to play the Star Spangled Banner and the audience
may get bored amd leave early.

Always used Bounce on my SW rig while doing domestic work like that. just take about three or four Bounce sheets, rub the entire outside of the radio and antenna. If you have your antenna up on a tower, clinb the tower and rub the antenna down really well. Do the feed line and the whole tower and the ground system. Now the key to it all. Take the SW radio completely apart and rub the sheets all over the insides - even the batteries! This, you will see, works wonders on static cling. I have stuffed every thing I have over here with Bounce sheets and I would never go back to using Downey again. Bounce works best, period!

> Tnx.

Robert OM,

See any of Doug Demaw's books or articles. There are dozens of designs
for low power amps using bipolar and mosfet devices. I have found
books to be of more use than looking for a specific schematic file
on the WWW. Your local library may also have ARRL handbooks, which
will contain at least one design you are looking for. You want
a complete explanation of the theory of operation, mechanical
arrangement, etc, as well as supporting design and operation description
text. In my experience, if you just try to duplicate a design from a
schematic only, your chances of success are greatly diminished.

73 and GL,

Don W6JL

Would love to trade it for QRP equipment and/or
other measuring instruments.

Got two SS5702 Jiwatsu,
Dual Trace,
DC-20MHz,
4" X 3" blue display,
Backlit graticule,
20 V to 1mV settings,
with calibrate settings,
bought used, works fine,
nice.

If no trade then I would like to get $200.00 for one of them.

If you would like to make a reasonable offer
reply via email only, stiwari@cwonders.com

Tnx

Rich,
What's the part number of the Matsushita RF reed relay ?
My little brain is to lazy to work it out,that you problably know
off hand....What speed relay is needed for QSK up near 40wpm ? Or a
better question, would be the total "circuit" speed needed, input,
bias, output ?

Thanks, Bob

As I said to someone else, if you go to Microsim's website and fill out a simple form, they will send you a free CD with a circuit size limited version of their entire development suite.

I use the schematic capture and PSpice and parametric optimization for crystal filter design.

I haven't tried the autorouter and other pc board stuff, yet.

As long as you are aren't designing something with 100 IC's and transistors, it will probably work for you.

Rob.

GaAsFETs are primarily used for extremely high frequency, low
signal amplification projects. By extremely high frequency, I mean GHz
not Mhz. GaAs FETs certainly have low injection or "shot" noise, and
should work fantastic for this application albeit a bit overkill. :)
Most RF amps use JFETs for the initial gain stage, Bipolars for the rest.

> I haven't measured the gain of the
>
> thing because I don't have the equipment, but it nicely hot.
> Nonetheless, it's aggravating to be plagued with RFI.

Amplify the signal, means amplify the noise as well. :) There
is a way around this, have you ever thought about designing a purely
MAGNETIC influence antenna? Some hams from years past have played around
with these designs, nothing more than a VERY large ferrite rod, wrapped
with a faraday shield to eliminate the electrical component, followed by
a shielded amplifier and delivery system (coax). These types of antennas
are very directional however, but this can be an advantage if you are
trying to pick a weak signal out of a stronger one. Since this type of
antenna only receives the magnetic field of the transmitting station,
and rejects all electrostatic fields, noise is GREATLY reduced. Imagine
SW with the clarity of local AM broadcasts! Now you see what I am
talking about here! I'm suprised nobody is marketing this type of
antenna today! For example, when you use this type of antenna, that
60Hz buzz from your neighbors TV disappears. Power transformer noise
also is greatly reduced if not completely eliminated. Lights with
dimmers that used to make terrible buzz when they come on would now
only produce the turn-on pop. The design is simple, wind a resonant
tank (inductor and variable capacitor) onto a very large, high Q ferrite
rod, shield in chicken wire, mount in a movable base (very directional,
so you need to move it to pick up different stations), connect to a
standard RF amp design, which is mounted inside the case, and you're
there! The most expensive part is the large hi-Q ferrite rod.......sq

(if there would be a market for such a device, I might design a version that would be "for consumer use" and put it out for sale. Sorry, Mr. TinyTenna, don't mean to horn in on your busines, but.....)

3701. Turning off amp

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-03 00:00:00 UTC
From: Tom Taylor <ttaylor@adobe.com>
Message-ID: <33443CE7.6F0C@adobe.com>
Source record: 95368

A couple of years ago I built a homebrew dual 4-400A amp based on some plans from the 1978 (approximately) ARRL Handbook. I use the amp fairly often and it seems to work pretty well.

The amp has four staged switches for turning the various parts of the amp on in an orderly manner: fan, filament, high voltage, operate. When I turn the amp off, I turn each stage off in reverse order. After I turn off the HV, it takes a little while to bleed off the HV from 3200v down to 0v. I usually wait until the HV is zero before turning off the filaments. Is this wait necessary? Can a 4-400 be damaged from HV on the plate with no filament heating?

Thanks,
Tom Taylor N7TM

:R4-C well separated from the DDS, no commong power supplies that were
:not well decoupled, DDS output fed via coax, etc. I am building a DDS
:for my recently completed R2 receiver here. From looking at the
:spectral output of the DDS, I cannot see how it should result in the
:symptoms you describe, but I could be wrong, as I have not actually
:tried it yet.

Assume your DC receiver's MDS is -130dbm. Assume that you use an RF amp
with just enough gain to offset other losses, maybe 8db.

Now you have a mixer being fed with LO with close-in spurs -70db down from
a 1v DAC output. Injecting the spur at the LO port of the mixer is the
same as injecting a similar spur on the RF IN port at the rf input freq.

So its equivalent to a "spur generator" hooked up to the antenna with spur
levels at -70db from 1v. So your spurs are huge compared to any signal
input.
Even if your spurs were -100db down, youd still have problems.

Thats why no ham equipment manufacturers use DDS, except as an elaborate
part of some hybrid scheme using PLL's.

Rob.

3704. Homemade External VFO

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-03 00:00:00 UTC
From: David McKain <mckain@cemr.wvu.edu>
Message-ID: <3343B5C4.7349@cemr.wvu.edu>
Source record: 95371

A friend of mine is proposing to me that I can build an external VFO for
my Kenwood TS-520S.
I was interested since the current VFO doesn't seem to stay stable
(spring tension, warmup) and,
unlike most of the newer HF rigs, my radio is not a general coverage
reciever (1.8,3.5,7,14,21,28,28.5,29.1) +600KHz.
The chip that he suggested is only about $20 and will oscillate from 0
to 40MHz with a sensitivity of
less than 0.006Hz. I would use an RS-232 port to control the chip and
write a small software program
to operate as the VFO controller.

Has anyone had any experience trying to do this?
Any suggestions would be appreciated (except to by another rig)

I bought some surplus 470 uF 450 VDC Rubycon electrolytic
capacitors recently and have a couple of questions on using
them.

I don't see a vent hole/plug - do they vent up ("blow their top)
or down?

I'm amazed at their small size (about 1 3/4" H by 1 1/4" Diam).
Is this a typical package size for 470 uF at 450 V nowadays??
(want to leave room for replacement in future)

Thanks for your help. I don't want to build them into a project/
repair incorrectly.

73,

John W0DC

The radial caps often lack a venting hole and as far as the size is
concerned that doesn't sound right at all!
I just replaced some caps in an old receiver using 47 mike at 450 and
they were are inch and a 1/4 diameter and inch and a half long or more.
They were pretty fat. That was just for a 47!

Caveat: For various reasons, the audio phase shifting is not precisely 90 degrees, and it's a bit different in the T2 exciter. Has to do with driving impedance. I have a little paper by Rick following up some of these questions (from the kit supplier, N8ET).

Bottom line: your RF phase shifting has to be tweakable, as much as 91 degrees or so. There are also variations in the mixers, probably more subtle, but still real.

> Noise figure is around 12
> dB.

I take it you read some of the modifications. My original R2 board has been cobbled to include the NE5532 op-amp stage after the preamp, like his later miniR2 and like the Technical Correspondence piece he published later regarding noise figure improvement (I eliminated the emitter follower while I was at it).

> Kenwood TS820.

The 820 has a PLL to clean up the VFO, does it not? Same with the QST
DigiVFO -- he put it into a Drake TR7.

Noise is too high also. The DigiVFO article (March 1996 QST) shows noise
only 80 dB down close to the carrier. Too close to the dynamic range of
the mixers.
If it doesn't beat this, it's worse than a good analog VFO. Definitely
need the PLL.

For a receiver, any spur above the noise is problematic. the DigiVFO's
close in spurs were about 55 dB down, the others 70 dB. No good.

A 1K resistor placed between the GND and ANT terminals should
prevent this from happening in the future. If you notice any loss
in sensitivity (you shouldn't with that high of value) use an even
higher valued resistor.

Source record: 95249

On a note totally unrelated to DDS's:

I built my own receiver after the Cambell article first came out. It ran 80M to 10M using a helical resonator VHF vfo. :) :) No joke.

I then took the vhf signal and divided it down using 74AC74 and gates as switches. This signal went to the digital Quad generator using two more 74AC74.
Band was selected by a BCD front panel switch.

On 15M I take the 40M signal and triple it. All this sounds complicated, but it did fit into a relatively small box.

I sold the receiver to a friend years ago, and he still claims its his best sounding receiver.

Oh, and also, I used a front panel control for tweeking the phasing, so that good sideband suppression could be obtained on all bands.

Rob.

ps. one thing that definitely helped in building the rcvr was an abundance of mil 1% caps that I put in series parallel or whatever to get the values I needed for the diplexer.

Dale I have a tuner that has relays in it -- one switches the tuner
in/out. Other relays select three output for different antennas/balun.
The tuner is made in UK and I don't know anything about the relays
except they are quite small - enclosed in plastic and accoding to the
manual good for 3KW peak. They should have little if any effect on
VSWR.

Hope this helps.

Hi

Looking for a discussion, or pointers to a reference, that gives a good practical discussion of the ins and outs of tuning duplexers in the VHF and UHF ranges. I'm also interested in test equipment requirements and variations in tuning procedures that may affect results.

Source record: 95253

I�m making a microwave pre-scalar which will connect to a frequency counter. The device I�ve chosen is the MC12079 (it�s good to 2.8 Ghz, any other suggestions?). The chip needs an input from -15 dbm to +5 dbm, and anything over 15dbm can destroy the device. Now, I�d like to have a larger dynamic range. How do I limit microwave signals?

I think I would use a cheap ERA-3 MMIC pre-amplier, and even if it goes into saturation, it should drive the pre-scaler just fine. However, the ERA-3 has a Max input of 13 dbm, and I�ve like to limit my signals to avoid burning it out. Just how much power might I throw at it? maybe 30 dbm.

How does one limit microwave signals ranging from -60 dbm to +30 dbm to 0 dbm?

thanks,

Allen Wallace

Have you heard that the FCC has made available 350 megahertz of spectrum
(READ BELOW).

I'm looking for some tech weenies experienced in building homebrew
equipment.
I want to sit down and start developing some wireless LAN equipment
utilizing this newly liberated airspace. I very experienced in the
LAN/WAN technology but I lacking in hands on, hardware design,
experience.

Think of it! A wireless LAN device, cheap to manufacture, that would be
inexpensive enough for every household in America to purchase. Forget
these money grubbing telcos. If we can supply the technology cheap
enough we can build our own wireless Internet and minimize the
dependency on the telcos.

Any takers? Any dreamers? Any entrepreneurs willing to take a chance?

Drop me a line if interested!

-Andy

*****

COMMISSION PROPOSES TO MAKE SPECTRUM AVAILABLE FOR USE
BY NEW UNLICENSED EQUIPMENT;
NII/SUPERNet Devices Would Facilitate Interconnection to NII
(ET Docket No. 96-102)

The Commission has adopted a Notice of Proposed Rule Making to make
available 350 megahertz of spectrum at 5.15 - 5.35 GHz and 5.725 - 5.875
GHz for use by a new category of unlicensed equipment called
NII/SUPERNet devices. The Commission stated the proposed rules would
foster the development of a broad range of new devices, stimulate the
growth of new industries, and promote the ability of U.S. manufacturers
to compete globally by enabling them to develop unlicensed digital
products for the world market.

NII/SUPERNet devices would provide short-range, high-speed wireless
digital information transfer and could support the creation of new
wireless local area networks (LANs) as well as facilitate access to the
National Information Infrastructure without the expense of wiring.
These devices may further the universal service goals of the
Telecommunications Act by offering classrooms, libraries, health care
providers, and other users inexpensive networking alternatives which may

access advanced telecommunications services.

3722. Help: Part specs???

Newsgroup: rec.radio.amateur.homebrew

Message-ID: <5i3vbe$qdc@news1.mnsinc.com>
Source record: 95257

Can someone help me decide which scheme is best for cathode keying of a typical medium tube power xmtr?

I can use either of three parts to pull this off but I am not sure of their maximum voltage ratings.

TWO of them are small 14-pin DIP relays, and the other is a power transistor, which is type TIP22

The relays are:

GUNTHER
3570 1210 053
07-93 Date code

TELEDYNE
641-1

The voltage I need to be able to switch is typically up to 200V DC or a little more in the un-keyed condition.

The relays are designed for 24 V DC or 120V AC service respectively, but I have no idea what the max ratings would be.

The TIP22 is used to switch 24V DC solenoid valves so I am sure it has plenty of current handling capacity. They typically drive the TIP122 with an iso-optical/darlington device like the 6N139 from HP.

Anyone have any specs on these? Or recommend which I ought to be using between my CMOS keyer's bipolar 2N2222A NPN output transistor and my cathodes of the old 1625s etc. ??

I really don't want to go find a horizontal output transistor, as I would rather use what is already in the junk box here!

It SEEMS like the relays would be the best way to go since they are probably fast enough for up to 35-40 wpm and could still be also used for grid-block keying if called-upon for that duty too at some point!

Regards - Bry, G3XLQ / AF4K

>
>

Well, greetings from "the horses mouth".

I got such a kick out of reading all of the comments I thought I'd stop by and say HI to my fellow BAers.

Since some are interested in "why" there is another list for the BAs it's simple. I believe (and I'm allowed that pleasure) that on the Internet the mail lists should be free. If it cost to much to run it for free, find another way to run it or simply don't. I'd hate to see a trend started...although I'm sure it will happen. Now, do I think you need to "believe" I'm right? Nope....but I expect the flames anyhow.

Is it run by the City with the strange looking City Hall...that same City that brought you the Super Bowl 1996 and brings you the Fiesta Bowl each year? Yep. Do you think that football stuff cost any tax money? Hmmmm...I think SB XXX cost us about $200,000.

The reason the "Radio" groups are on our server (we also host the Collins and Heath lists) is mainly for testing. We bought a list server software package for $2,000 that we needed to learn how to manage - and test. You can't test a package without running some live data though it...hence the "ham" lists. It worked...we found some bugs (just ask the Collins guys), and at this point we think we have them all crushed. We are already starting to populate the server with some "city" lists now and we feel good about its operation.

Tempe is a big supporter of ham radio - giving us meeting rooms for our club, places for VE testing, and recently a classroom for ham classes. We are installing a station in the adult center and they donated a 2 meter repeater that we maintain on one of the City sites. Don't you wish YOUR City was as "ham friendly"? Enough about the host for the list server. As far as tax money...I see any tax money that "we actually get to make use of" as a good thing!! And who wouldn't?

You'll notice that I have not been pushing the subscription to the Tempe BA list...heck, I work for a City, and as a civil servant I'm sworn to not care if you live or die. Just kidding....but my attitude is...if enough people want it it will fly...if not, it won't. Time will tell. Meanwhile it's an option...not a stab at the other list (that I'm a member of by the way - and enjoy)...not an ego boost...but maybe it is the thing that I can offer to my fellow hams.

Let's get back to talking about radios that warm the shack and the heart!

Sure sounded good though, didn't it?

>>(the latter equates to more of the
>>older equipment (and tubes) being saved rather than being
>>dumped into landfills!).

> Mixed metaphor/s? "the latter" (as phrased) is not clear
>to me. Nevertheless, I agree totally with the basic thoughts.

"The latter" was supposed to refer to the new folks who had never
sub'd to the paid list. They might not have been interested enough
in BA gear to have paid to sub, but now with a free list (and all
its exposure!) hopefully their interests will have been sparked
into salvaging gear found in the garage, basement, attic, neigh-
bor's garage, et cetera. Our worst nightmare is hearing of old
gear and crates of tubes being tossed into a dumpster. If it takes
a second list to help save some of the older equipment from extinction,
then so be it.

Don't forget that in the past years, everytime someone on the BA list
brought up the idea of going to a newsgroup format (such as we now
have here), almost everyone else would shout "NO! It will dilute
the group!" It took going to a paid subscription to bring about
the creation of this rec.radio.amateur.boatanchors forum. And
mention of a future $20/yr fee (one week of meals for me),
tempe.gov simultaneously created the free BA, Heath, and
Collins lists. I believe we're better off now having all
these wonderful nets.

Thanks to the info provided by group members, I was able to replace the front end FET on my DX-390 receiver. Popped an MPF-102 from RS in there and the receiver came back to life. It is always very satisfying to fix a reciever - especially when it is one that you have grown accustomed to using. (I'd been using the 390 to listen to 160 meter QSOs at bed time.)

Anyway, thanks to all those who provided info... and watch out for that static!

Ah, that myth! The idea that man made noise is predominantly
electrostatic has been around for a long time. It may even have
been true for an earlier generation of technology, but it isn't
now. Computers, in particular, tend to make noise that's predominantly
magnetic.

This isn't to say that magnetic antennas aren't useful, but they
are no miracle cure for noise pickup. In a noisy environment where
one cannot block common mode on the feedline a balanced magnetic
antenna will likely outperform an unbalanced electrostatic (whip)
antenna. However, compared with a *balanced* electrostatic antenna
it may be worse.

True, but the computer generated noise seems to be blocked by
my 8" ferrite rod antenna. :) It also seems to eliminate lightning
pops, which when my longwire is installed show up as deafening pops and
crackles. However, my 8" ferrite antenna is not a performer like my
longwire. Give and take I guess.

Does anyone currently sell magnetic antennas? I built mine out
of theory, nothing much to go on except old textbooks, but the theory is
simple enough, who needs plans. ;)

This is true only in the near field of the noise source within
lamda/(2pi), on 80 m the limit is 27 m. The closer to the noise source
you are, the greater the difference between the electric and magnetic
field, at 0.01 wavelengths the difference is about 20 dB.

Responding to: jeffreyh@Hawaii.Edu (Jeffrey Herman)

Jeff:

You make some very coherent arguments in debate but,
obviously, I cannot agree with all. Rather than rehash all,
I'll pick up on your closing paragraph with some additional
comments.

>What do you feel was done that is unethical? Choice of name?

Unethical may have been too strong but an identical choice
of name for BA list at Tempe is totally foolish IMO.

>The name is generic.

Not quite! Certainly the PHRASE is generic but the
application is NOT. Tempe's choice is foolish for another
Mail List because it causes confusion for those that are seeking
the "Boat Anchors Mail List" when responses from helpful persons
will point to one or the other; either way, IDENTITY is DILUTED.

>Free venue?

This very newsgroup (alt.radio.amateur.boatanchors) already
gives "free venue". Is there something wrong with this? The
"third prong" from Tempe brings confusion and seems to add
nothing more.

>It gives those who've left over the past 12
>months another forum to participate in, and brought in new
>folks who had never sub'd to the paid list (....)

Where are your data? ;-)

Please review the just immediate paragraphs. Your statement
seems to me to be more of personal philosphy than
_reality_of_purpose_.

>(the latter equates to more of the
>older equipment (and tubes) being saved rather than being
>dumped into landfills!).

Mixed metaphor/s? "the latter" (as phrased) is not clear
to me. Nevertheless, I agree totally with the basic thoughts.

-=Tony=- W6ANV San Francisco, CA

ps: I find it strange that the "owner" of the Tempe BA list
is not participating in the exchanges here. If he/she is,
he has not ID'd as such to my knowledge. I'd like to hear
(read) what HE has to say. "From the horses mouth", so to
speak. So would others like to read, I presume.

I know that the design is tremendous overkill. I wanted to get as
close to "long wire/passive" as humanly possible. Granted, it may
turn out that I'm optimizing something which really doesn't need it.
Could be kind of like worrying about the effect of Pluto's gravity on
the tides, I dunno. . ;) Actually, the amp works great on my scanner,
which is one of the first places I tried it.

>(if there would be a market for such a device, I might design a version
>that would be "for consumer use" and put it out for sale. Sorry, Mr.
>TinyTenna, don't mean to horn in on your busines, but.............)

I hadn't considered loops thus far. One thing I had thought about
though was twin whips, on the theory that a lot of noise would be
common-mode, but I'm afraid a lot of the signal might be common mode
too if the whips aren't resonant, or at least long enough. :(

As for directionality -- unfortunately, that's a minus for a roof
mount antenna on my budget (and with my apartment restrictions!) :(

Thanks for some ideas. I may toy with the loop idea anyways, since I
have heard they can work exceptionally well in many cases.

See the R2 RECEIVER thread about DDS VFO problems. You cannot use a DDS directly for receiving applications; noise and spurious responses are too high. It has to be cleaned up with a PLL after it.

Now, that can be qualified a little bit. I have a flyer for new, cheap DDS's from Analog Devices. The AD9850 clocks at 125 MHz, so it should generate up to 40 MHz or better. Its spectrum has few spurs above the noise, but the noise in only about 80 dB down. You might get by with that with an older transceiver like the 520, (maybe it's better than I think, dynamic range wise), but that's right on the border for any modern design with a diode ring mixer.

The other problem: you gotta watch out when you stretch the range of a transceiver by just changing the VFO input. What problems are you going to get into with the rig's heterodyne scheme? Tuned circuit tuning ranges? Etc.

Hi,

I am in need of information on the 2SC2879 & 2SC2290.
Who makes these? Where can I get data sheets for these? Who sells
these in sets of 2 or 4 at a reasonable price (I can currently get
the 2879 for $23.00 ea and the 2290 for $18.50 ea)?

Finally, why should I use these instead of the MRF454?

Thanks,

KO4LW

There have been some excellent articles on this in QST over the past
few years regarding the DDS type VFO/synthesizer units.

You can build your own or buya kit of parts from Engalnd or from S&S
Engineering in Maryland.

>
> Rob.

Hi Rob,

I think I am beginning to see your point! IF the mixer is a true
multiplier, then of course the complete spectrum of the LO is able to
mix with the input signal, and all resulting spurs will appear in the
output. In fact, having an otherwise very clean front-end, with high
dynamic range, demands a very pure LO signal indeed. Seems like one
needs an LO with spurs at least as far down (in terms of equivalent
uVolts RMS at the input the mixer), as the minimum detectable signal, to
avoid hearing the spurs in the output.
Where I was going wrong I think was in thinking of the LO as a high
level, saturating drive which merely turns the diodes on and off in the

ring mixer, very hard. If the LO is cancelled (say by 40 dB or so), in the output, due to the balanced nature of the ring mixer, then I thought that the LO spurs would also be similarly attenuated.
Still scratching on paper about this...

73,
Don

At the time Heath made HW-8 kits, perhaps not. But that was a long time ago. *Now*, in 1997, with so few hams doing any construction of any kind, I'm prepared to be a lot more lenient on the definition of "homebrew", and hope others would be too.

I have no idea which direction the capacitors vent.

Be aware that the smaller packages in general have higher ESR, and
lower ripple current ratings.

You may never have a problem with heat or deterioration from ripple
current, but it is potentially a worse problem with the smaller caps.

I have the following stuff for sale:

Canadian Marconi military radio transmitter.
Transistor with dual tube final stage.
Transmitts around 400Mhz in FM
Puts out about 100W
$100

Racal-Dana digital programmable function generator.
HPIB
$400

HP signal generator
3.8Ghz to 7.8Ghz
Tube, in excellent condition
$150

Ail-Tech 727 Spectrum Analyzer
1Mhz to 20Ghz in 5 ranges or 1-20Ghz in one sweep
missing CRT, but easily hooks up to scope
$500

RF Communications laboratory amplifier.
10-500Mhz
8W output
transistor, tube final stage
$200

Tek 5110 scopes. 3, one storage
6 plug-ins
4-channel; 100Mhz, depending on plug-in
$600 for all

Boonton Radio Co. signal generator
10-500Mhz, AM and FM
Beautiful piece of old tube equipment
$100

Boonton Radio Co. signal generator
54-216Mhz, am and FM
another beautiful old piece of equipment
$75

Telequipment transistor testing scope
$100

HP 6180A Waveforn Recorder
2-cannel digital storage scope. Uses external screen (scope)
HPIB
$400

HP 182T analog scope
100 Mhz, 2 channel
beatiful scope
$350

HP 1630A logic analyser
5 pods
HPIB
$500

HP 493A microwave amp
4-8 Ghz
$150

HP 54201A Digital storage scope
300Mhz
HPIB
one channal is dead, otherwise works great
$500

3 Superior Electric indexing stepper motor drivers
12A, chopping
$300 for all

2 CompuMotor stepper drives
$200 for both

Stepper motors, ask

I live in CA, Santa Clara and prefer local buyers. Call me at (408)
244-6607 or e-mail me. Prices are flexible. I prefer volume buyers. $4000
takes all.

The change from near field to far field is a gradual change, not an
abrupt one.

But I do agree with Paul and others that "magnetic antennas" are a
myth. The signal you hear at any distance at all, whether the noise is
from a NATURAL transmitter like a lightning discharge, a MAN MADE
ACCIDENT like a electric motor , or an INTENTIONAL transmitter is all
the same to the antenna.
```

If the antenna only responded to magnetic fields, you would hear no distant signal at all. If it responded to electric fields, the same would be true.

In the near-field (that distance is also determined by the size of the noise source antenna and receiving antenna size) either a near field magnetic dominant or near field electric field dominant antenna might be better.

But make no mistake about it, once the noise is from a very small distance away it makes no difference what the near field response is like. Only the PATTERN of the antenna will control noise response. It is also impossible to build a magnetic or electric field only antenna, stop one field and you stop the other.....completely.

>How does one limit microwave signals ranging from -60 dbm to +30 dbm to 0
>dbm?

I designed the "C channel" of the HP 5334B frequency counter. This
was a prescaler channel good from 90 MHz. to 1.3 GHz. What I did
was put a small resistor in series with the input connector; I think
it was around 50 ohms. This had two pairs of Schottky diodes connected
from the resistor to ground. This same node went to the first
preamplifier. It was important to use SMT Schottky's not the leaded
ones due to lead inductance. Anyway, this could withstand at least a
watt of input power if the resistor was good for a watt. It limited
cleanly, so that the counter still worked OK. If you try to limit
by overdriving amplifiers, they typically screw up your signal, unless
they are balanced amplifiers. In any event, like you say, 1 watt
will burn out most amplifiers.

Is it in a metal shielded enclosure? That would at least help.

Ideally I suppose locating it near the antenna would be best, but as
you noted there are several drawbacks. If the lead-in is Coax, you
probably won't notice that much difference from a noise standpoint.

If you decide to put your preamp near your receiver, and your
listening room doubles as your computer room you will probably want to
put the amplifier in a metal box to shield it. You might also try to
eliminate the RFI by putting Ferrite beads around your Computer
Monitor's video cable, that was the worst offender on my system. It
helped, but did not eliminate the problem.

Locate the AM trap before the Preamplifier, so that strong AM stations are attenuated before they hit your preamp. Better to filter them out early, and only amplify signals in the range you're REALLY interested in.

>3. Would a hybrid approach be worthwhile? I'm thinking of putting

I doubt that coax loss will be that great unless you're running it a LONG way. Ideally, you want as much gain as early as you can get it in the system, so you minimize the amplification of noise. As for the rest, I'm starting to like your idea of locating the amp near the radio.
;-)

I guess you could run extra control lines to the amp and control the bias on the GaAsFETs remotely to alter their gain. You're going to have to run DC power and Ground to the amp anyway. (or are you using batteries??)

I'm not familiar with your circuit, or the GaAsFETs you're using, so its tough to say. Another option would be to use a relay to remotely switch amplifiers in/out of the circuit as need be to prevent overloading the front end of your receiver or the later stages in your pre-amp.

This "is it homebrew" issue keep cycling around every so often. There just arnt that many EE's in the ranks that can sort out why one needs to put which part where. I am also not fond of mail
ordering to seven different parts houses to get what it is that I need. If someone wants to make up a kit and put it on the market Than to me this is a good thing. Please remember that I am the one
who has to build the kit and I am the one who has to make it work. I may not have designed the circuit but after 3 kits I sure know how to read one and each kit has been an excellent learning tool.
Is it hombrew, who cares.

From: lar01@sprynet.com
Message-ID: <33467351.17026891@news.sprynet.com>
Source record: 95271

Greetings
I commented, a few weeks ago, about getting a cordless phone. A couple weeks, after the purchase, I discovered it was a 44 mhz phone. I commented to both motorola and radio shack, via, email that the phone was somewhat missadvertised. In the advertising, there was no meantion of frequency used yet it was on the same page as new 900 mhz units. I figure a natural mistake, even for an amateur, hi/chuckle. I took the cordless phone back to radio shack, who were very nice and,

realising my error, replaced it. I bought the sanyo clt-9261, the only one in the store of 900 mhz operation. I advertizes to use spreadspectrum and 900 mhz. I hope i am right this time, hi.
I many reason for the purchase was to educate myself about the style of operation even though it is very 'close circuit'. As time goes on I would like to get more familiar with spread spectrum. Personally

i think that spread spectrum will eventually replace traditonal radio like vhf fm replaced traditional local contact coverage on amateur radio during the 70's and 80's.
Any observations/comments from anyone else?
Larry ve3fxq

>up a lot of questions:

Some RFI is short range, just an E field or just an H field, but
if the source is large enough to form an effective antenna, or is
connected to wires in such a phase that the Poynting vector is
synthesized, an EM field, IE ordinary radio wave, will be generated,
and that can propagate long distances.

>1. Should I put the amplifier up with the antenna? If I do this it

The feed impedance of a short voltage probe antenna is very high.
If you use a direct coax feed, your signal will be lost to the
coax capacitance. The first stage preamp needs to connect directly
to the antenna.

>2. I need some sort of an AM filter to keep from overloading the
>preamp. Should that go in front of the first stage, or after a stage
>or two, or should it be at the receiver (I'm worried maybe the coax
>will pick the AM back up even if I'm very careful to filter it at the

A filter *after* the preamp contributes nothing to preventing preamp
overload. But as noted above, the impedance presented by a short
voltage probe antenna is *very* high, and matching to a filter before
the preamp first stage is very difficult. A solution is to make the
preamp first stage a source follower. This will act as an active
impedance transformer and can then drive a more conventional filter

before the second and third preamp stages (which can then be of more conventional voltage gain configuration).

Good coax, driven with a source impedance matching the coax characteristic impedance, and terminated with an impedance matching the coax characteristic impedance, should be adequate to avoid BCB pickup. If you have common mode problems, one of the RS snap together ferrite chokes should take care of that.

>3. Would a hybrid approach be worthwhile? I'm thinking of putting

You can certainly do that. It's a good division of resources.
Be sure to get a good source match to the coax.

F6AGV/TPK 1.82 Msg #:1247 Le 5/03/97 a 15:56Z

Bonjour merci de lire ce message,
Il y a un certain temps, j'ai realise un detecteur electrostatique
avec un transistor a effet de champ (2n3819) et quelques transistors
(2n708...). La detection se traduisait par l'allumage d'un voyant.
Ce montage fort simple a ete un peu ameliore depuis, mais son principe
de base est reste le meme : l'utilisation d'un FET, transistor a effet
de champ. (grande impedance grille/source).
Une description est apparue dans le RADIO-REF de Novembre 93, sous la
plume de Michel F9VX. Des articles ont ete publies dans differentes
revues comme ELEKTOR : electrometre...champ electrique...ions...
Des articles tres interessants sont apparus dans le bulletin des
physiciens sur le principe physique des detecteurs electrostatiques.
Quelques experiences sont decrites, tout ceci donne l'envie de
realiser un petit montage tres facile a faire et surtout tres
amusant avec la participation des enfants et de la famille.
Les phenomenes magnetiques sont bien connus de tous ; on possede tous
quelques aimants puissants comme la partie magnetique d'un vieux
haut-parleur. La boussole met en evidence le champ magnetique
terrestre : le pole Sud de la boussole est attire par le pole Nord
de la planete.

En ce qui concerne les phenomenes electrostatiques, les choses sont bien plus mysterieuses a priori, et on ne realise pas vraiment que nous sommes situes en permanence dans un champ electrique.
Sauf les personnes qui habitent sous les lignes a haute-tension !
Parfois, on est confronte au probleme des charges electrostatiques, qui peuvent avoir un effet nefaste, en particulier pour les composants electroniques. D'ou l'utilisation des emballages speciaux anti-statiques. On a tous ete intrigues par les charges accumulees sur l'ecran du televiseur familial, l'attraction de petits bouts de papier avec un stylo en plastique, le sous-vetement genre "moi froid jamais" que l'on retire dans le noir, la decharge sur la portiere du vehicule ou les arcs echanges avec notre chat prefere.
...
Plus grave, l'utilisation d'une moquette dans la station radio peut avoir des effets destructeurs et de nombreuses pannes mysterieuses peuvent trouver leur origine dans la presence de fortes charges electrostatiques invisibles mais dangereuses (au sol ou sur le bureau).
Vous avez peut etre ete surpris par un petit arc entre votre clavier 102 touches et votre doigt arrive a quelques millimetres d'une touche. C'est rare mais cela existe.
Le detecteur d'orage, qui est en fait un "detecteur d'influence electrostatique" mettra bien en evidence tous les phenomenes presents autour de vous et beaucoup d'experiences feront la joie de votre entourage. Ne pas trop maltraiter votre minet quand meme !

A signaler, tout de suite la forte charge accumulee par les bouteilles d'eau (vides) en plastique, qui serviront par la suite comme charges disponibles pour effectuer les tests du detecteur. (mise au point).

Mais, l'utilisation la plus spectaculaire est encore la mise en evidence des charges atmospheriques a proximite ou meme situees au dessus de nos tetes, on realise alors que les nuages si charmants vehiculent en permanence des charges electriques plus ou moins importantes et de signes positifs ou negatifs.

Pour fixer un peu les idees, sans faire un cours de physique, la terre et les couches ionisees de l'atmosphere forment un enorme condensateur, la terre etant negative, avec une tension de l'ordre de 300 a 400000 kV,
pour la ionosphere par rapport au sol pris comme reference.
Ce qui fait, environ un champ dans les 130 V/m au niveau du sol, tension et champ non mesurables avec un simple voltmetre .
Les conditions atmospheriques changent constamment et les nuages qui vehiculent des charges se polarisent par rapport au champ electrique terrestre, c'est a dire charges positives dans la partie inferieure et negatives dans la partie superieure. (normalement).

Certains nuages sont neutres ou echangent des charges avec la terre, par exemple les montagnes ou le relief. On assiste a des phenomenes d'influence ou des transferts de charges (courants electriques).

Ainsi, vous pouvez tres bien etre en danger sur une montagne, si vous etes pris dans un echange de charges entre un nuage et le sol, par simple effet de passage de courant a travers le corps. (pas encore la foudre). N'oubliez jamais que nous sommes conducteur du courant. La resistance moyenne d'un individu se situe au alentour de 1000 Ohms. Pour les phenomenes plus violents comme la foudre, il s'agit par exemple, de nuages d'orage de type cumulonimbus, dont le sommet se situe a environ 12000 metres a -50°C et qui accumulent une energie colossale. Sans rentrer dans l'explication meteorologique pure qui n'est pas reellement terminee, (voir les tornades ou la foudre en boule, par exemple), on peut constater que les charges electriques positives se situent dans la partie superieure etant donne les forts courants ascendants et les charges negatives se situent vers le bas du nuage. Le sol se charge positivement par influence.

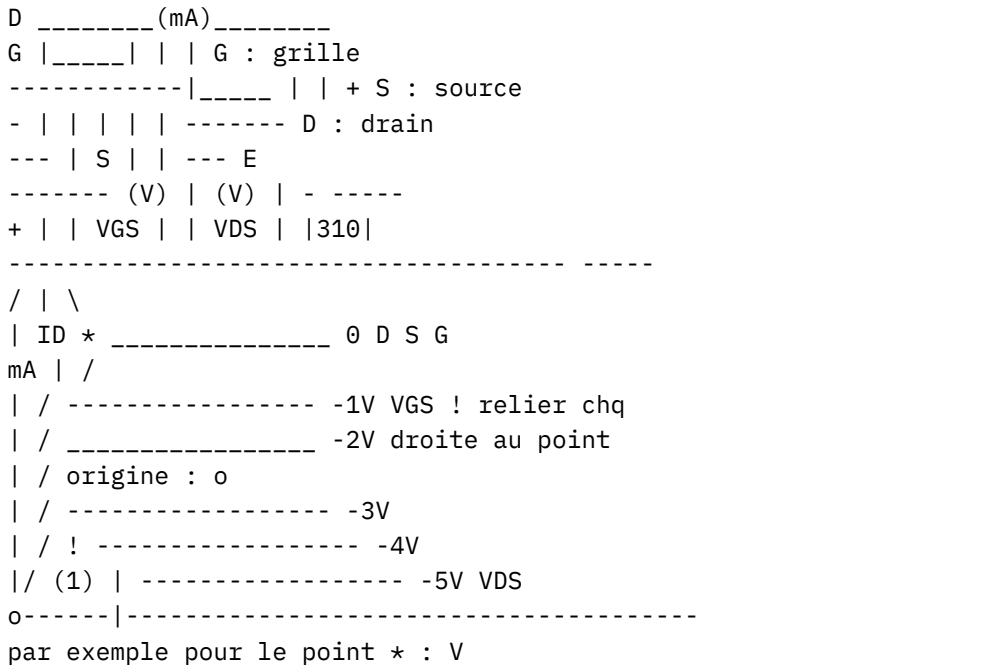
Il y a donc, des decharges electriques (eclairs) entre les parties electriques differentes du ou des muages et le sol.
Tout depend de l'importance de la charge accumulee, de la tension entre les elements de charges differentes et bien sur de la distance et de l'hygrometrie de l'atmosphere.
Le detecteur d'orage sera donc sensible aux eclairs, il permettra de prevoir l'arrivee de l'orage ou signalera un danger possible de decharge electrique locale. Longtemps a l'avance, le detecteur signalera l'activite electrostatique de l'atmosphere, les orages lointains alors que le ciel est parfaitement degage, et le flots de charges positives a l'avant de la masse orageuse.
Nous aurons donc un detecteur capable de donner l'alarme en vue du debranchement des antennes. (en version alarme).
Cette question est suffisamment serieuse, pour que l'on daigne s'attarder a trouver une solution et a mettre au point un detecteur fiable qui ne sera pas considere comme un gadget amusant pour des experiences futiles. C'est un veritable appareil de controle.
Je pense a tous ceux qui ont eu des degats importants dans leur station, ou meme ressenti comme moi le "courant passer" en faisant des essais d'antenne verticale dans le jardin, quand la foudre est tombee non loin de la. Pensons aussi aux nombreux equipements calcines des stations repetitrices situees sur les points hauts, comme par exemple le relais du Roc de Gourdon ou les batteries eventrees jonchent le sol et les cables coaxiaux grilles donnent une idee de ce qui est arrive a l'interieur de la cabine.
Tous les temoignages seront d'ailleurs bienvenus...
Le detecteur n'empechera pas la foudre de tomber ou elle veut, mais il donnera une indication et une alarme, c'est son but.
Voir la suite, pour le principe du montage et la realisation.

NB : Pour la petite histoire, les OMs se reconnaitrons,
non, il n'y a pas de vipere autour de la cabane !?
mais le sol est surement vitrifie, par endroit...

Sans plus attendre nous allons passer a la description du detecteur d'orage ou "detecteur d'influence electrostatique".
Par la suite nous pourrons revenir sur la theorie et examiner quel-

ques experiences ou vos resultats et impressions.

Le transistor a effet de champ : type J 310
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
C'est l'element principal du detecteur, un transistor a effet de
champ canal N, du type FET (ou TEC) : field effect transistor.
On peut realiser un petit montage pour etudier ce transistor et
relever ses caracteristiques : ID



par exemple pour le point * : V

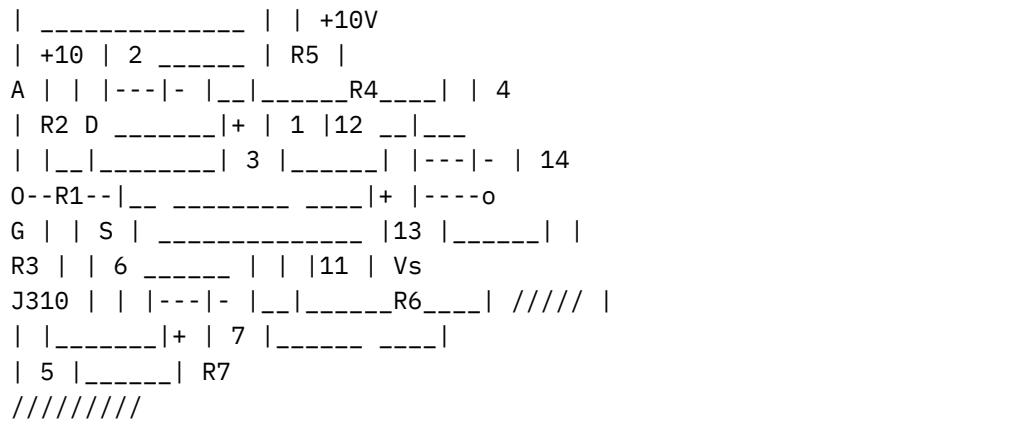
ID = 0,65 mA, VGS= 0 et VDS= 1V
On peut deduire de la caracteristique ci-dessus que le transistor
est une resistance variable dans la zone (1), du point o au point *
le reglage se fait par action sur la tension VGS.
en appliquant la loi d'Ohm :

VDS 1
Rfet = --------- = --------- = 1538,5 Ohms a VGS = 0
ID 0.00065

Cette resistance est faible, elle peut meme etre de quelques Ohms.
Si on applique une tension negative et de plus en plus negative,
entre la Grille et la Source, la resistance Rfet augmente et elle
peut atteindre une tres grance valeur, le courant ID s'annule.

On peut expliquer ce fonctionnement en examinant la structure
interne du transistor : le canal, mais ce n'est pas le but, on
admettra que le canal qui laisse passer le courant du Drain vers
la source s'etrangle plus ou moins suivant la tension negative VGS.
Avec VGS, negatif par exemple -8V, le canal bloque le courant ID.

Schema de base : installer le transistor dans un pont diviseur,
~~~~~~~~~~~~~~
//////

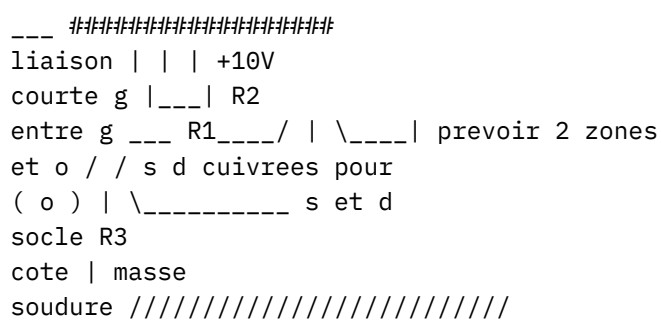


Antenne Pont div. montages suiveurs soustracteur
0,5m J310 LM324 LM324
inox
Placer l'antenne sur une embase isolee (O) par exemple SO239 teflon.
L'extremite etant vissee sur une fiche banane male.
(possibilite de changer le type de l'antenne).
La tension de sortie de ce montage varie entre 0 et un maximum.
Les suiveurs sont presents pour bien isoler le pont diviseur.
Le soustracteur nous donne en sortie :

Vs = VD - VS = VDS et VDS depend de VGS.
donc de l'etat de l'antenne.

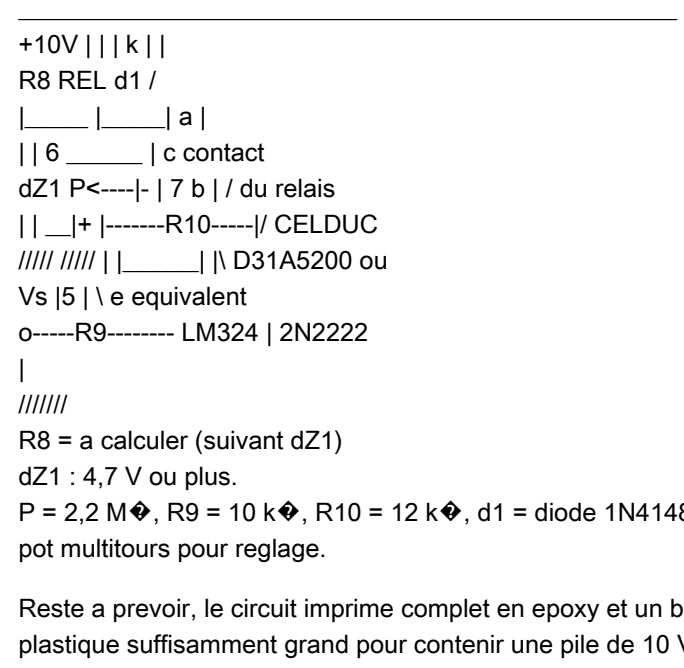
Les resistances sont :
R1 = 10 M&#65533;, R2 = 2,7 k&#65533;, R3 = 1 k&#65533;, R4=R5=R6=R7= 4,7 k&#65533; Alim : 10V.
(une tension de 9V peut convenir, ou meme 12 V).

Attention : les resultats dependent du bon isolement de la Grille et
de l'antenne, le transistor sera soude cote cuivre ou mieux installe
sur un support de transistor a proximite du socle S0239 :



Vue cote cuivre : R1,R2,R3 et support J310.
~~~~~~~~~~~~~~~
Montage pour alarme :
~~~~~~~~~~~~~~~~~~
La sortie sera dirigee vers un montage de mise en forme dans le but
de donner une tension de 0,6 a +4,6V de facon a attaquer un voltmetre
ou une interface vers un PC (il faudrat prevoir une isolation dans ce
cas avec un opto-coupleur par exemple). description a suivre.

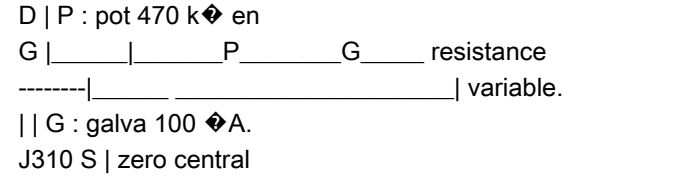
Elle peut se diriger vers un montage d'alarme par depassement d'un
seuil reglable, qui declenchera un circuit exterieur, voyant,sirene...
par exemple :



R8 = a calculer (suivant dZ1)
dZ1 : 4,7 V ou plus.
P = 2,2 M&#65533;, R9 = 10 k&#65533;, R10 = 12 k&#65533;, d1 = diode 1N4148 ou eq.
pot multitours pour reglage.

Reste a prevoir, le circuit imprime complet en epoxy et un boitier
plastique suffisamment grand pour contenir une pile de 10 Volts.
Dans ce cas, la tension chute relativement rapidement et au bout
d'un certain temps le montage ne fonctionne plus, mais pour une
utilisation exterieure il faut prevoir l'emplacement d'un bloc de
piles ou un accu. Voir le probleme de l'alimentation secteur et la
protection par VDR eventuellement.
On pourrait prevoir un galvanometre de 100 &#65533;A en serie avec un pot.
de 470 k&#65533; a commande externe, comme moyen de controle visuel.
Ce montage est a relier entre D et S du J310 directement sur le
circuit imprime, prevoir des picots par exemple.
Derniere chose, tres importante la face superieure du boitier
plastique doit etre recouverte de papier d'aluminium en contact
avec la masse de la SO239, pour eviter un effet capacitif par
accumulation de charges sur le plastique.
La description est terminee, la realisation peut commencer.
Eventuellement je peux vous proposer les plans et une photocopie
du typon contre ETSA, ecrire REF-ARAN-59, qui transmettra.
~~~~~~~~~~~

Une petite explication sur les premiers tests a effectuer avec le
detecteur d'orage.
Placer par exemple le galvanometre pour observer l'influence
electrostatique des charges environnantes :



~~~~~~~~~~~

ou non.
Voir schema precedent : (2).
La pile ou l'alimentation 10V etant branchee, approcher une charge
negative de l'antenne du detecteur. C'est la bouteille d'eau minerale
en plastique (vide bien sur !) qui constitue une forte charge negative.
Le galvanometre doit devier a fond et la tension de sortie est forte.
Que se passe t-il ?
charges : - et + attraction
__ _ __ _ - et - repulsion
____-__-__) |+ + et + repulsion
----> |+ antenne
charges |+
negatives | ID
| Ig | D ^ 100 0
|__<___|--- | \ <-- Vs = maxi
- - - |--- S |VDS \
VGS | | \
///// GALVA

Les electrons (-) de l'antenne sont repousses vers la grille du FET.
Celui ci se bloque et VDS augmente, d'ou le courant dans le galva.
VDS
Igalva = ----------
P
Une tension VGS negative est donc presente ce qui rend ID faible
proche de zero, et VDS augmente vers la tension de la pile.
Si la charge est fixe, au bout d'un certain temps le galva retourne
a zero : les electrons diffusent dans la resistance d'entree du FET.
Elle est de l'ordre de 10+12 M�.
En eloignant la charge il ne se passe plus rien, si elle s'approche
a nouveau il y a une nouvelle deviation du galvanometre.

Important : la distance entre l'antenne et votre bouteille "etalon"
doit etre la plus grande possible, le detecteur doit reagir et
sa sensibilite est fort grande pour une distance de plusieurs metres.
Sinon, verifier l'isolement de l'antenne (tige inox verticale 0,5 m)

Si on approche une charge positive de l'antenne (verre charge),
rien ne se passe, par contre en eloignant le verre, il doit y avoir
une deviation importante :
La charge positive attire les electrons vers le haut de l'antenne,
la grille est donc positive et le FET est conducteur, comme il etait
deja conducteur avec VGS = 0, rien ne se passe en sortie ou sur le
galvanometre.
Par contre en eloignant la charge positive du verre, les electrons
refluent vers la grille et bloquent le canal.
Meme phenomene que plus haut.

Votre detecteur fonctionne donc parfaitement, et des deviations
rapides se produisent quand il est a l'exterieur. Reste a regler
le seuil de l'alarme, suivant le temps orageux ou pas.

Pour cette derniere application il est possible d'amortir un peu
les variations en placant un condensateur chimique en sortie Vs.
(avec une resistance aux bornes de 47 k&#65533; par exemple pour la
decharge du condensateur).

Vous etes donc pret a faire quelques experiences chez vous ou dans
la nature, par exemple a proximite des pylones a haute tension.
(attention quand meme a ne pas vous mettre en contact avec les
tensions du reseau EDF !!!)

Il serait interessant de disposer de charges positives ou negatives
connues avec un condensateur plan que vous pouvez charger vous meme.
Prendre 2 disques en carton et recouvrir une face avec une feuille
d'aluminium que l'on trouve dans la cuisine. Demander a votre YL !
Le disque inferieur sera pose sur une plaque de polystyrene, face
alu au dessus et le disque superieur sera pose exactement au meme
endroit mais avec une feuille de papier intermediaire.
(pas de feuille de plastique, ou polystyrene ...)
Coller un corps plastique de stylo pour pouvoir deplacer le disque
superieur sans le decharger avec les doigts.
En reliant les disques a une tension continue, vous pouvez charger
votre condensateur plan avec la charge que vous voulez :

S m&#65533; Surface
Q = C . U et C = &#65533;o.&#65533;r -------- disque
Coulomb Farad Volt Farad e m epaisseur
papier
-12
&#65533;o = 8,854 10 permittivite du vide

La permittivite du papier sec &#65533;r = 2,5
" " de l'air &#65533;r = 1,0006
" " du verre &#65533;r = 5 a 12

(La rigidite dielectrique de l'air est 3000 kV/m environ).

Un disque sera positif et l'autre sera negatif quand vous les
separerez.
Suivant la polarite de la pile utilisee.
Fixer le fil de liaison souple denude sur l'aluminium avec un adhesif.
Pour le disque sans poignee, l'autre sera charge avec une pointe de
touche au bout d'un fil.

Voila, terminee cette description j'espere que vous aurez toute
satisfaction notamment en ce qui concerne la detection de l'orage.
Vous pouvez faire un autre detecteur pour les experiences.

Une antenne avec une partie pliee a 90&#65533; ameliore la detection :
Faire les essais, prevoir une protection en extremite (petite boule
en aluminimu par exemple : voir x).
x x--------
| |

| |
verticale | |
simple | repliee |
| |
o fiche o fiche

Une liaison antenne vers detecteur par coaxial ne semble pas convenir
en raison des pertes et fuites dans les isolants.
Le detecteur exterieur doit etre protege de la pluie, d'ou la boite
electrique etanche grise utilisee....et l'antenne inox...

73 de Alain F6AGV@ON1LJA.#TY.HT.BEL.EU

Toutes remarques et resultats bienvenus, merci,
Vivement l'orage pour tester le detecteur !

:Hi Rob,
:
: I think I am beginning to see your point! IF the mixer is a true
:multiplier, then of course the complete spectrum of the LO is able to
:mix with the input signal, and all resulting spurs will appear in the
:output. In fact, having an otherwise very clean front-end, with high
:dynamic range, demands a very pure LO signal indeed. Seems like one
:needs an LO with spurs at least as far down (in terms of equivalent
:uVolts RMS at the input the mixer), as the minimum detectable signal, to
:avoid hearing the spurs in the output.
: Where I was going wrong I think was in thinking of the LO as a high
:level, saturating drive which merely turns the diodes on and off in the
:ring mixer, very hard. If the LO is cancelled (say by 40 dB or so), in
:the output, due to the balanced nature of the ring mixer, then I thought
:that the LO spurs would also be similarly attenuated.
: Still scratching on paper about this...
:
: 73,
: Don

I think the true answer is somewhat murkier than my oversimplification. Certainly any two spurs or LO to spur with a difference in freq somewhere in the audio range will show up in the audio output. But its probably very hard to predict their level due to to port to port isolation and any other wierdness in the mixer and diplexer. You'd probably need a supercomputer since it seems the DDS manufacturers haven't totally figured out how to predict spurs in their products either.

Still, though -70db minus another -40db for port isolation still equals a loud signal.

I have never tried a commutating mixer in a DC receiver. It seems you'd need an audio transformer on the output and some kind of network so that it would act like a real transformer also at the LO freq.

Best regards, Rob.

True, but non propagating near fields are usually the worst problem in residential EMI, and the power transfer to antenna due to non-propagating magnetic fields decrease as 1/r^3, whereas the electric decreases as 1/r^2...also magnetic loop antennas that are highly symmetric in geometry and loading exhibit deep narrow nulls and broad maxima in 3-D so that by rotating and tilting the loudest self-coherent local magnetic noise source (usually line related noise or CRT noise), whether propagating or near field, can be reduced by 20-30 dB with little effect on polarization scattered ionospheric reflected signals or most groundwave signals which happen to have somewhat different azimuth and/or polarization. A short dipole has an end fire null too, but in my practical experience (inadequate balance?) it is not close to a shielded magnetic loop null in depth or sharpness.

Hi,
I'm trying to breath some new life into an old Icom 720A transceiver by replacing the faulty rotary relay in the band pass filter unit.
Working on an article written by WB0GAZ in 1993 I'm hoping to replace the relay with indivdual band switching relays, of which some 14 are required (to switch filter input and output).
Space constraints dictate these relays should be as small as possible, which then limits the current rating of the relay.
The question is, am I right in assuming the current rating of the realy can be calculated (using formula P=I^2 R, P=100W, R=50ohms) to be 1.4A, and therefore a relay rated at 2A AC will work, or am I missing something?
Put the question another way, what relay current rating should I use to handle 100W?

Thanks

It's an either-or, as are most all semiconductors. The current rating
alone tells you that it can dissipate at least .6*200A or 360W, into
some kind of heat sink probably. If it went linear at 500VCE and 600A,
it would be smoke.

According to Faraday's law, a changing magnetic (H) field creates an electric (E) field. This E field, if it is tangential to the surface of a conductor, appears also as an induced emf *in* the conductor (if the conductor is not a perfect short circuit) by virtue of a boundary relation for tangential electric fields. This is the law of electromagnetic induction (Maxwell's equation derived from Faraday, also known as the the transformer induction equation).

The magnetic field, by itself, doesn't induce *anything*. Changing magnetic fields don't induce voltages directly, rather it is the associated E field that is responsible.

This principle is very commonly found in conventional transformers of all kinds, where the magnetic flux is nearly *all* found in the high permeability core, but the windings are physically separated from the core by air and insulation. The flux itself doesn't come in contact with the wire (except for a tiny amount of leakage flux), but the E field does. In a transformer, the only requirement is that the conductor must *enclose* the magnetic flux.

This reasoning also applies to the counter-emf that is induced back into the primary winding of the transformer.

One of the major misunderstandings of electromagnetics is that the magnetic flux itself is *directly* responsible for induced emf. Not true at all.

This reasoning also applies in general also to antennas.

> would be true.

No. An antenna may respond to either magnetic or electric fields
in its vicinity, or some combination. A short dipole is relatively
insensitive to magnetic fields, while a small loop is relatively
insensitive to electric fields. *Radiated* fields have equal energy
in their electric and magnetic fields, but the quasi-static fields
very close to an EMI source are often predominantly one type, so
an antenna that's unresponsive to that type will have a signal to
noise ratio advantage.

Paul Keindnen wrote:

> you are, the greater the difference between the electric and magnetic
> field, at 0.01 wavelengths the difference is about 20 dB.

If you replace "is true" with "could be true" in the above you're
right. Note however, that the field in the "static" zone within
lambda/(2Pi) of the radiator may be predominantly electric,
predominantly magnetic, or a combination.

Formulated in terms of dipole moments in the "Gaussian" units
commonly used by physicists, the radiation equations for a small
dipole and a small loop are perfectly symmetrical: you just exchange
electric dipole and magnetic dipole moments, and electric and
magnetic fields. Thus, there is no preference in the physics for
a particular dominant field: which will dominate depends on the
particulars of the situation.

Jim (stubstad@ix.netcom.com) wrote:

> the power transfer to antenna due to
> non-propagating magnetic fields decrease as 1/r^3, whereas the electric
> decreases as 1/r^2

The *field strength* (not power transfer) behaves like this when the dominant field in the static zone is magnetic. However, you seem to be assuming that the 1/r^3 behavior means the magnetic field energy drops below the electric field energy. Actually, when they get to be comparable (at about lamda/(2Pi), as Paul said), the slope becomes shallower and they remain comparable through the "induction zone" (out to about lambda) and the "radiation zone" (where they become almost exactly equal).

Power transfer is proportional to the *square* of the field strength, so dipole-dipole or loop-loop power transfer declines like 1/r^6. Loop-dipole or dipole-loop power transfer is smaller in the static zone, but it only declines as 1/r^4. In all cases, the fields in the radiation zone (far from the radiating antenna) decline as 1/r and power transfer declines as 1/r^2.

Jim (stubstad@ix.netcom.com) also wrote:

> A short dipole has an end fire null too,
> but in my practical experience (inadequate balance?) it is not close to
> a shielded magnetic loop null in depth or sharpness.

I think you've hit a real issue: in some cases it is easier to balance a loop antenna than it is to balance a dipole. One common practice that is sometimes not best is to use a multifilar "balun" transformer for balancing an antenna. A conventional transformer with separate windings often achieves better balance, especially if it is wound on a relatively small core. It is harder to get good symmetry with a balun. I once introduced a balun into an already well balanced scientific video system ("just to make sure") and made the balance worse.

Myron,
Their are several ways to link these repeaters. They all rely
upon the controller to be able to perform the needed functions. Most
controllers in use to day are microprocessor controlled and will
handle several types of links.

The Easiest if a Simplex link on a say 70cm. For a more transparent
system you can use a Full Duplex link on 70cm.

I can get into a more detailed explination on the links if you would
like.

Hi Bill,
You might want to rethink your design. If you are using a common power supply for the RF and modulator sections, a 2:1 turns ratio will only allow 70-75% modulation. I would triode-connect the 813's in the modulator or go with 810's,805's,or811A's and use a ratio of 1.4:1 or so. Just a thought from an old fart who's been there.
Congratulations on being a builder, it's a dying but very rewarding part of the hobby. Hope to hear you on Yayem.

Dale,

There is a cad program called KeyCad by Softkey (available at wal-mart) for about $30 that has a good symbol library. Its a little quirky to learn but works well. If you want to spend a little more money and get up into a real cad program, AutoCad LT costs around $400 and has extensive symbol libraries available. From there you can go all the way and spend around $3500 for AutoCad Release 13. The same libraries that work for this will work for LT. Unless you want to do 3-d work, there's no real reason to buy the big package.

Try a Schottky / hot-carrier diode like the 1N5263.

The article regarding using an oscilloscope CRT for lightening detection lead me to write the author and ask if a TV set CRT could also be used. He said yes, the deflection coils would go to N-S and E-W oriented dipoles. Well this now leads me to ask, can one use a TV as an oscil-loscope? It certainly would be crude but it might be fun to convert and use, just the same.

Based on my experience with some equipment we used to manufacture, no
one makes 50 Watt Zeners any more. You can replace your 50 watt unit
with a 50+ Watt power transistor and a smaller Zener or just string a
series of smaller voltage Zeners that add up to 24 V.

Boy -- that brings back memories! It certainly is possible. I remember seeing adds back in the 60s for info on converting tvs into "big screen oscilloscopes" in magazines such as Popular Electronics, etc.
I assume they used the horizontal deflection circuits in the set, and applied the signal to the vertical deflection amplifiers. I would think the bandwidth and the sweep capabilities would be limited.

Hi Gary,

The E and H fields are effects we measure, they are not the *cause* of
the radiation field.

The radiation field is caused by acceleration of charges. It is
impossible to "synthesize" an EM radiation field.

Thinking the electric and magnetic fields are separate physical
"things" that can be mixed or picked apart when dealing with radiation
is the source of much antenna voodoo.

> associated E field that is responsible.

True, but misleading in this case. The question at hand is whether one can make a difference in pickup of local EMI by selecting a small (compared to lambda/(2Pi)) loop antenna versus a small dipole. Whether you consider the loop response to be due to Curl E or dB/dt is irrelevant, since you get the same answer in either case. The important thing is that the loop does not respond to curl-free electric fields. The field of a small dipole antenna, in the static zone, is nearly curl-free so a loop will be relatively insensitive to it.

> This principle is very commonly found in conventional transformers

A conventional transformer represents the extreme case of two loop antennas coupled in the static zone. Those who believe that there's no difference in static zone pickup between dipoles and loops are invited to attempt to build a working transformer with a dipole in place of one of its windings.

Tom Rauch wrote:

> Thinking the electric and magnetic fields are separate physical
> "things" that can be mixed or picked apart when dealing with radiation
> is the source of much antenna voodoo.

In the static zone (well within lambda/(2Pi) of the field source) one *can* treat the fields as separate entities. This is a "long wavelength" approximation, but remember that Maxwell's equations themselves represent a long wavelength approximation of quantum electrodynamics, which is a long wavelength approximation of electroweak theory, which is... Well, you get the idea.

Farther away, you can indeed get into serious trouble with this approximation. Most types of antennas are bigger than the static zone, so this approximation is not generally useful in antenna design. However, the subject is active antennas, which are normally small enough, and close enough to EMI sources, that this approximation *is* useful.

I'm just getting into ham radio, and I feel that I should learn about the componenets of ham radios before I go on. I want to learn about antennas and hopefully make my own.

I was wondering if someone has schematics (or a list/description) for making a VHF antenna, recieve only, omni etc.

I am looking for something that will recieve between 79 Mhz and 1500 Mhz (ironically the same frequencies which FM is broadcasted over... I suppose you can tell what I plan on using this antenna for).

Also, what are the particular things that make an antenna recieve better signals from farther away, or transmit different frequencies and range.. Does anyone know a good on-line resource, or perhaps a book that I could find at my local Coles Bookstore or Library?

Anyway, if it looks like I have no clue what I am talking about, I don't so don't make fun of me! :)

Thanks everyone, this group is great!

> this sound reasonable? Any comments appreciated.

For packet, NONE!!!! You arent worried about it in this application as in
x.25 1200 baud, you only have TWO freqs to consider...1200 and 2200Hz.
For voice applications, 6db/octave is the standard value....the reference
freq is 1000Hz for 0db gain...
For 9600 baud and other FSK, you dont use pre-emphasis either! DIRECT FM
the TX...

Actually if you register it, you get 220 pin capacity...and its STILL Free!! I have 1.26 now....works great under W3.11 and 3.1...
DONT Forget to get the WIN32s files needed to run it under 3.1x

The bandwidth is about 6 MHz, and that can be extended to maybe
10 MHz without too much work, but the sweep is the real problem.
You can't deviate very far at all from 15,750 Hz for the horizontal
deflection because the flyback circuit (which makes HV for the CRT)
is resonated at that frequency and is an integral part of the horizontal
deflection system. For a 19 inch set, that gives about 3.26 microseconds
per inch as the sweep rate. That's pretty fast for the sorts of signals
an oscilloscope with a vertical bandwidth of only 6 MHz would normally
observe. It's too fast for most audio work, and ironically it is too
fast for most TV service work where a deflection factor of 5 mS per
division or 20 uS per division would most commonly be used to observe
the vertical and horziontal waveforms respectively.

If you could decouple HV generation from horizontal sweep, as is done
in multisync computer monitors, then you could be more liberal with
your horizontal sweep rates, and produce quite a usable instrument.

They fed a signal into the video that was timed and referenced to the
horiz. What you got was a vertical running waveform that you either had
to turn your head 90 degrees to see or turn the TV set 90 degrees (lay
it on its side) in order to see the waveform.. It was also only good for
audio frequency waveforms. I would not consider it today.

Hi again, Rob,

Just an update on my experiences with DDS and an R2 receiver.

At a friend's QTH here in San Diego where I am visiting this week, we
tried my R2 receiver using a DDS as the LO, built up out of a discrete
10-bit DAC, and discrete phase hardware and 16 MHz system clock. We
checked the output spectrum of the DDS on a spectrum analyzer and, at
7050 KHz output (getting close to 1/2 Fclk), we measured spurs only 45
dB down within 2 MHz +/- of the output frequency. When connected up to
drive the mixers in the R2 at the same level as that of my homebrew
colpitts LO, there was no detectable difference in reception noted,
switching rapidly back and forth between the two.
The receiver hears 1uV weakly, with either LO.
We tried listening on the AM BC band, (several transmitters nearby),
and it worked perfectly with the DDS as the LO.
We tried listening with no input selectivity whatsoever (no
preselector), to weak sigs on 40M SSB and CW, and again, could detect by

ear, no discernable difference in signals or noise level between the DDS LO and the analog VFO, driving the R2.
In short, we heard no birdies or other noise covering up weak signals. The DDS did have an internal LPF on the output set to 14.3 MHz. The DDS was originally intended for another non-ham application, and was tunable only by a DTMF keyboard entry, so we could not check operation while changing frequency (no continuous tuning). The DDS was enclosed in its own metal cabinet, with BNC output.

My conclusion is so far that DDS should work fine with the R2. I hope to have my own DDS using an AD9830 (50 MHz clock) running soon at my home QTH.

I am interested in any other inputs from those of you who have had experience using DDS directly as the LO for a receiver. Use my HP e-mail address, not the one shown in this message, which is my son's new e-mail address in San Diego.

73,

Don, W6JL

A "longwire" is only half an antenna. What's the counterpoise (Earth
ground? Your AC line?)? Unless installed and fed with care, a
longwire is highly susceptible to pickup of common mode EMI from
the AC line. See "Low Noise Antennas" at <http://www.grove.net/~badx/>.

AOR and Palomar make them. Pretty pricey. Save your money and build
your own (more fun anyway).

Im looking to simply draw schematics and wiring-interconnection diagrams. PC layout would be nice also, but not an immediate requirement for me.

I have downloaded from ivex.com and must get back to their shareware program for 100 pins. I am not aware of what is meant by "pins". Does that mean a count of pins on IC components or a count on terminal points for all components?

I think the thing to do would be to use *two* yoke coils. Take the existing yoke, leave it connected, but pull if off the crt and secure it up and out of the way. (My understanding is that at least in the older sets, one of the yoke coils is associated with HV generation) Next, take a junk-box yoke that fits the neck of the tube and slide it on.

Now, you're completely isolated from the electronics of the set, and have full control of the sweep. It does mean, however, that you've got to come up with some external drivers for those coils. Also, I imagine you would want to do do something to the video to keep the beam from being modulated.

3804. Morse Code Questions: Timing relationships

Newsgroup: rec.radio.amateur.homebrew

From: NOSPAM.pfriedr@azstarnet.com
Message-ID: <NOSPAM.pfriedr.78.0017F053@azstarnet.com>
Source record: 95319

I'd like to tinker with a microcontroller algorithm to decode Morse Code. What I 'd like to know is whether anyone can tell me what the various timing relationships are.

For example: I believe that a dash is three times as long as a dot. In terms of "dot timing", how long is the interval between letters? Words? Is there any additional time between sentences? If an operator is sending, say, 10 wpm, what is the actual length of the dot (in seconds)?

Please email if you can help. Note that my return address has been spam-proofed. Delete the "NOSPAM." from the beginning of my address.

Thanks in advance. Pete

Want to make MONEY fast?????

A little while back, I was browsing these news groups, just like you are now, and came across an article similar to this that said you could make thousands of dollars within weeks with only an initial investment of $5.00! So I thought, "Yeah, right, this must be a scam!" as most people probably thought. But also like most people I was curious, so I kept reading. Anyway, it said that you send $1.00 to each of the 5 names and address stated in the article. You then place your own name and address in the list at #5, remove the #1 person, and move everyone up a position, and post the article in at least 200 news groups. (There are more than 18,000 of them). No catch, that was it.

So after thinking it over, and talking to a few people first, I thought about trying it. I figured what do I have to lose except 5 stamps, envelopes, sheets of paper and $5.00, right?

Like most of us I was still a little skeptical and a little worried about the legal aspects of it all. So I checked it out with the US. Post Office (1-800-725-2161) and they confirmed that it is indeed legal.

Then I invested the measly $5.00.................

Well GUESS WHAT!!!.. .Within 7 days, I started getting money in the mail! I was shocked! I still figured it to end soon, and didn't give it another thought. But the money just kept coming in. In my first week, I made about $20.00 to $30.00. By the end of the second week I had made a total of just over $ 1,000.00!!! In the third week I had over $5,000.00 and it was still growing. This is now my fourth week and I have made a total of just over $20,000.00 and it's still coming in......

It's certainly worth the $5.00 and 5 stamps. I spent more than that in one week on the lottery!!!

Let me tell you how this works and most importantly, why it works... also, make sure you print a copy of this article NOW, so you can get the information off of it as you need it. The process is very simple and consists of 3 easy steps:

STEP 1: Get 5 seperate pieces of paper and write the following on each piece of paper, "PLEASE PUT ME ON YOUR MAILING LIST." Now get 5 $1.00 bills and place ONE inside EACH of the 5 pieces of paper so the bill will not be seen through the envelopes to prevent thievery (THIS STEP

IS VERY IMPORTANT!!!). Next, place one paper in each of the 5 envelopes and seal them. You should now have 5 sealed envelopes, each with a piece of paper stating the above phrase and a $1.00 bill inside. What you are doing is creating a service by this. THIS IS PERFECTLY LEGAL!

Mail the 5 envelopes to the following addresses:

1) I. Guest
1800 A Hillcrest Rd.
Columbia Mo, 65203
USA

2) B. Gelsleichter
RR2 Box 272
Tunkhannock, PA 18657
USA

3) J. Hurless
3649 Yorktown Way
Boise, ID 83706
USA

4) C. Lanning
101-1537 Burnaby St.
Vancouver, BC V6G 1X1
CANADA

5) A. Cole
2580 W. State Road 28
Tipton, IN 46072-9787
USA

STEP 2: NOW take the #1 name off the list that you see above, move the other names up (5 becomes 4, 4 becomes 3, etc...) and add YOUR NAME as #5 on the bottom of the list.

STEP 3: Change anything you need to, but try to keep this article as close to original as posible. Now, post you amended article to at least 250 news groups. All you need is 250, but remember the more you post, the more money you make! Don't know HOW to post in the news groups? Well do exactly the following:

FOR NETSCAPE USERS,

1) Click on any new group, like normal. Then click on "To:News", which is in the top left corner of the news group page. This will bring up a message box.

2) Fill in the SUBJECT with a flashy title, like the one I used, something to catch the eye!!!!

3) Now go to the message part of the box a retype this letter exactly as it is here, with the exception of your few changes. (remember to

add your name to #5 and move the rest up.)

4)When you're done typing in the WHOLE letter, click on "FILE" above the send button. Then, "SAVE AS..." DO NOT SEND YOUR ARTICLE UNTIL YOU SAVE IT!!! (so you don't have to retype this 250 times!)

5) Now that you have saved the letter, go ahead and send your first copy! (click the "SEND" button in the top left corner)

6) This is where you post all 250! OK, go to ANY news group article and click the "TO:NEWS" button again. Type in your flashy subject in the "SUBJECT BOX", then to the the message and place your cursor here. Now click on "ATTACHMENT" which is right below the 'SUBJECT BOX". Click on attach file then find your letter wherever you saved it. Click once on your file then click "OPEN" then click "OK". If you did this right, you should see your filename in the "ATTACHMENT BOX" and it will be shaded.

NOW POST AWAY!!!

IF YOU'RE USING INTERNET EXPLORER:

It's just as easy, holding down the left mouse button, highlight this entire article, then press the "CTRL" key and "C" key at the same time to copy this article. Then print the article for your records to have the names of those you will be sending $1.00 to.

NEXT

Go to the news groups and press "POST AN ARTICLE" type in your flashy subject and click the large window below. Press "CTRL" and "V" and the article will appear in the message window. ***BE SURE TO MAKE YOUR ADDRESS CHANGES TO THE 5 NAMES!!*** Now re-highlight the article and re-copy it so you have the changes...then all you have to do for each news group is "CTRL"and "V" and press "POST". It's that easy!!

THAT'S IT! All you have to do is jump to different news groups and ost away, after you get the hang of it, it will take about 30 seconds for each news group! ***REMEMBER, THE MORE NEWS GROUPS YOU POST IN, THE MORE MONEY YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 250***

Those plans were still being advertised in the seventies. When I was
in high school in the mid-seventies, someone at school either ordered
plans or asked me if it was worth ordering. I honestly can't remember
which it was. I guess I'm ready for the QCWA; back then I certainly
had an image of their members as being very old. I'm not as old
as I thought those QCWA members were back then, but I can join in
a couple more months.

Ham Radio magazine ran an article about a "spectrum analyzer" in 1972,
maybe March. It only sweeped the ham bands. It would scan each of
the hf bands individually, but they were displayed at the same time
Or rather, the technique gave that illusion).

What makes it applicable to this thread is that the display was a
converted tv set, which was converted into a limited function
oscilliscope.

I thought it was a neat project at the time, and the application
took advantage of the larger screen of the tv set while accepting
the limitations of the tv set.

Steve,

Would a ~6" long by ~1/4 ferrite rod taken out of a defunct am recvr
I have on hand (I also have a 2x1/2x1/8" bar), qualify as very large
hi-Q rod in your perspective? Or should one look for something much
larger e.g. 8"+ x 1/2"+ ?

Could you expand on "shield in a chicken wire" expression you used.
Is it only a figure of style that language barier dosen't permit me to
catch right on (native language is french (Quebec)) or have you got
something more specific in mind.

My undestanding of your reply is that everything (the ampli and the
cable) should be as well sheilded as possible, but the ferrite rod
itself should be 'only partly sheilded' through some kind of metalic
screen (of what specific type?) . Is that it?

Thanks for any info.

BTW I appreciate your input to this gr, your sense of humor and some
of the opinions you posted on religious matter.

Altough the essence of the latter should, IMHO, better be left to a
specific ng for those interrested in the specific matter (and I have
couple strong opinions of my own ;)), religious broadcasting being a
SWL reality, the subject ought to be address on its own merit in
relation with its SWL impact.

Hey!, the other day, just for the fun of it, I breadboard myself an xtal radio for SW band and all I could ear was someone vociferating " God WANTS you to do this... God WANTS you to do that..." and so fort (how the h... does he know that!?) and moving around I stumbled on mellow voices chanting their "Hail Mary full of..." That was it! Now I'm left with myself to desing a more selective unit (and I'm no designer!! :(). That's an impact! You see it? ;)

>> Sorry, Mr.
>>TinyTenna, don't mean to horn in on your busines, but.....)

You shouldn't be sorry about that Steve ;). Maybe he should get in touch with Ted. I think they would get along quite well oneanother, at least for the time of an email!. Unless both were the same and sole person, in which case he will get along quite well with himself, but that even, I doubt ;(

H.C.

BTW Ted, this maybe a fairly long reply but ain't a binary file which AAMOF I have never posted on this n.g. nor on any other for the matter. Asking informations on how to treat them when they come ain't posting them. So I don't want to see any of your trash in my mailbox or I'LL SUE YOU! (hehehe)

I have a new unused, except for testing, Eimac 4CX3000A tube, New Socket, and new Peter Dahl Filament XMFR available...never got around to building that " BIG ONE". This can be built grid driven so a 100 watt exciter will drive it till your coax melts (around 6 KW out). OR can be built more sensibly to put out any power level less. Directions and circuit information are available on the "AG6K Website".

I agree with Bryan: Find a copy of the American Radio Relay League's
Antenna
Compendium or Antenna Book.

To my way of thinking, there are three books each ham shack should have:
The ARRL Handbook for Radio Amateurs
The ARRL Operating Manual
The ARRL Antenna Book

Check out http://www.arrl.org/catalog/

Another good book to have is Bill Orr/W6SAI's Radio Handbook--I think it is

still being published...someone correct me, if I am wrong.

A well stocked library should have one or all of these.

Curl E and dB/dT are not two different things. They are exactly equal to each other. In other words they are *identical*. They are in fact *inseparable*.

> The
> important thing is that the loop does not respond to curl-free
> electric fields.

There is no such thing as a curl-free radio wave (noise or otherwise). Loop antennas can be analyzed from the standpoint of electric fields or magnetic fields and there is absolutely no difference. They are equivalent.

>

Quantum mechanics "snow-jobs" are impressive (I guess) but do not contribute to this topic.

Right on, Tom. No delete key on this one.

The wave equation for radio waves is derived directly and unambiguously
from Maxwell's two curl equations. They are absolutely inseparable.

The misunderstandings involved here are at the root of some of the
fallacies about rod and loop antennas.

Now if we want to talk about the *polarization* of an antenna, then
there are some interesting concepts about noise reduction.

I have a T1900 Toshiba laptop for sale or trade. 486/20, 4 meg ram,
200MB hd (doublespaced to 385MB), monochrome VGA, quickport
trackball pointing device, 14.4 PCMCIA fax/modem, briefcase style
carrying case.

Charging circuit is going out -- will boot from charged batteries,
but not from AC/DC adapter. After booting, AC/DC adapter can be
used. Won't charge batteries.

All for $300 plus shipping, as is, or would prefer trade for
Oscilloscope, >40MHz dual trace, with 1x/10x probe. Multi-band QRP
equipment also considered.

E-mail interest only, please. Snail address is no good in Callbook,
and I have no phone in my name.

If trade, we'll each ship our own stuff.

From Ham 'Accessories to Zones' the DX Reference Guide has expanded to
60 pages and 1277 links. An index is now available for quick clicking to
the subject desired.

The Technical Reference Page now includes links to Amplifier Theory,
SWR, S-Units, dB tables, Antennas and much more.

The origin of '73' and the term 'Ham' are covered along with some
dubious humor and links to a list of 'Famous Hams'.

DXpeditions past and future are summarized and linked.

An extensive search came up with around 40 ham and electronic kits,
components, and circuit boards for homebrew projects.

The Mega-Prefix list covers the weird ones and new UK calls.

Nifty, huh.

Vsat = 1.5V at 250A, H_FE 75 min at 600A, R_th_JC = 0.035 C/W (about 20 to 30x better than a typical big power transistor), S.O.A. allows 600A at 800V for 50us, and Pd = 3500W at 25C case! Hmmm, sounds like water cooling for maximum use to me!

A helical antenna will pick up both Vertical and Horizontal polorized signals although there will be some attenutation induced when compared to a Yagi with the correct polorization. Helicals come in Right or Left hand polorization, and either will function in the vertical or horizontal plane. Bruce

Hi Walt -- you are the first in 6 months to note this. These were taken
from one of the widely published Ham magazines (name omitted). I would
be most happy to correct them if you can supply the correct information
or tell me where they can be found.

Any help would be appreciated.

It might be able to be done...the 520S has an AUX position on the band switch. Not sure if the PA tubes can go that high in frequency...if they can, it should only be a matter of putting in crystals to get 6M out of the rig. How about it? Anyone? Sounds like an interesting idea! I once saw an article in the ham magazines about a guy who converted a CB from 27MHz to 50 MHz!

>
>
Depends... I assume you have a serial mouse and an internal modem.

The PC normally has two interrupts available for serial ports. One is required for the mouse and one is required for the modem (at least when you using the modem). I have had this problem many times, here are the best solutions I've found...

If you use you modem only in win95, your modem allows you to select interrupts other than 3 or 4, and you have another interrupt available then... Set you modem for COM3 and use the available interrupt (IRQ). I have often used the LPT1 (IRQ 7) or the LPT2 (IRQ5) for the additional serial port with success. Just disable the resource for the LPT port before making the changes. Once you move the modem, re-enable the com port.

The solution I most often use is to buy a bus or PS2 type mouse with an interface card. Set the card to an available IRQ, or steal an LPT IRQ. This frees up the serial port used by the mouse and will allow your modem to work with DOS based programs.

I have a new unused, except for testing, Eimac 4CX3000A tube, New Socket, and new Peter Dahl Filament XMFR available...never got around to building that " BIG ONE". This can be built grid driven so a 100 watt exciter will drive it till your coax melts (around 6 KW out). OR can be built more sensibly to put out any power level less. Directions and circuit information are available on the "AG6K Website".

Must mean a step size of 0.006 Hz here.

: See the R2 RECEIVER thread about DDS VFO problems. You cannot use a DDS
: directly for receiving applications; noise and spurious responses are too
: high. It has to be cleaned up with a PLL after it.

This sounds like a VFO rplacement for the TS-520, so it's only operating
in the region of 4.9 - 5.5 MHz. Wouldn't a AD9008 be reasonably clean
operated this far below it's clock freq?

Hi Rod!

OK ... here goes. My source is the *current* UK amateur license
booklet, published by the Radiocommunications Agency.

G England
GB Special Event Stations anywhere in the UK, Channel Is or Isle of
Man. (Not just England)
GD Isle of Man
GI Northern Ireland
GJ Jersey
GM Scotland
GU Guernsey & Dependencies
GW Wales

2E England (Novices)
2D Isle of Man (Novices)
2I Northern Ireland (Novices)
2J Jersey (Novices)
2M Scotland (Novices)
2U Guernsey & Dependencies (Novices)
2W Wales (Novices)

M England
MD Isle of Man
MI Northern Ireland
MJ Jersey
MM Scotland
MU Guernsey & Dependencies
MW Wales

GX, MX England (Clubs)
GT, MT Isle of Man (Clubs)
GN, MN Northern Ireland (Clubs)
GH, MH Jersey (Clubs)

GS, MS Scotland (Clubs)
GP, MP Guernsey & Dependencies (Clubs)
GC, MC Wales (Clubs)

The meaning of the numeral after the prefix is rather complex, but is related to the License Class. Class A = full privileges, all bands. Class B = no code, for 50 MHz and higher frequency bands only.

1. All calls with one-letter and 2-letter suffixes are Class A.
2. For calls with 3-letter suffixes:
2, 3, 4, 0 after the prefix signify Class A.
1, 6, 7, 8 after the prefix signify Class B.
(At present, there are no 3-letter-suffix callsigns issued containing the numeral 5 and 9)
3. These rules apply to Novices (Class A and B) as well as Full Licenses (Class A and B), but Novices are only allowed to use small sub-bands within the "full" allocations.
4. There have been many "oddities" in respect of GB (Special Event) callsigns, for example GB800, GB100, GB50, GB9, etc. For these calls, it seems "anything goes"! Special Event calls are issued by the RSGB; all others are issued by the Radiocommunications Agency.

Hope this helps.

Are you aware that there is a difference between a random length end fed
wire and a "long wire" antenna?

3852. Modern Electrolytic Capacitors

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-08 00:00:00 UTC
From: "Tom V. Pfaffenbach" <tvpfaffe@mail.delcoelect.com>
Message-ID: <334A5959.2419@mail.delcoelect.com>
Source record: 95168

There have been many improvements in electrolytic caps since the days of aluminum FP and WP caps. The bases are solid plastic now, (no rubber vent plug to rot) scribed to crack and release internal pressure if necessary. It is almost never necessary, as current chemistry eliminates much of the former leakage and "forming" current, reducing internal heating and pressure build up. You can also use higher value equalizing resistors if you are hooking up those 450V units in series for a HV DC supply application. Check out the manufacturers specifications in the applications notes presented in the Digi-key, Mouser and Newark catalogs. Lots of neat information there!

>Has anyone done it ? Any IDEAS ?
>Thanks in advance de Isaac, 4Z4TL

In theory, it could be done. You'd have to wind your own heterodyne oscillator coils, transmit driver coils, receiver front-end coils, etc. You'd have to determine a new tap point on the PA tank coil. You may have to use different capacitance values in the PA tank. You'd need heterodyne oscillator crystals. Sounds like a lot of work. The PA will definitely work at 6m, and it should put out nearly full power. Still, it would be a lot of work.

If you undertake this project, keep complete and accurate notes. This would make an excellent QST Magazine article.

73 and good luck!

3854. Is it "homebrew" or "homebuilt"?

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-08 00:00:00 UTC
From: k5dh@dlep1.itg.ti.com
Message-ID: <5idnvu$oba@sf18.dseg.ti.com>
Source record: 95170

This question keeps popping up, and there are many viewpoints on the subject. I personally don't think any one answer is the right one. In fact, the whole issue is probably a waste of time, but, whatever.

In contests sponsored by most of the QRP clubs, a rig is considered "homebrew" if YOU built it, whether it was from a kit or from your junkbox, whether you designed it or not. In the eyes of these QRP clubs and organizations, if you didn't build it, it isn't homebrew.

I personally build rigs from kits, and also from designs that I find in books and magazines. I tend to refer to these rigs as "homebuilt", rather than "homebrew", because I didn't actually design them.

In some cases, I have made significant modifications to someone else's design, but because I was not the original designer, I refer to these rigs as "homebuilt" also.

I'm sure this debate will rage on until we're all ready to scream, but at least I've had the chance to add my two cents' worth.

73 to all, and whatever you do, keep on building!

announce

Space Arts Workshop '97

On April 13, 1997, a select group of artists and scientists from around the world will be gathering in Paris, France to discuss the social and cultural aspects of exploring space.

Seventeen individuals will be presenting their works of art, speaking as artist as space explorers. Among these people, is artist Arthur Woods whose work, "Cosmic Dancer" flew aboard the Mir Space Station. Also speaking will be Richard Kriesche, artist of the first art project in the history of the Russian space flight, to fly aboard the space station Mir (1991).

The event will be broadcast over the Internet via Maximov Publications Special section on the Mir Space Station (http://www.maximov.com/Mir/). You can view the preliminary pages at

http://www.maximov.com/Mir/mirspaceart.html

The space arts meeting is being organized by ars astronautica, Leonardo - the Journal of the International Society of the Arts, Sciences and Technology, Maximov Publications, and the OURS Foundation.

Workshop members will go online to answer questions from users (April 13, 1997 at 4PM to 9PM GMT).

During the event, Amateur Radio Operators around the world will be relaying questions to cosmonauts aboard the Mir Space Station. In order to get the questions to amateur radio operators we are asking for submissions before April 13th.

*** CALL FOR QUESTIONS ***

We are requesting questions for both workshop members and cosmonauts. Please submit your questions to Mark W. Curtiss via email (mcurtiss@excite.com) or via the online form (http://www.maximov.com/Mir/mirspaceartstalk.html). Results for these pages will remain posted at this site for future reference.

Thank you

Kenwood made a matching transverter for the TS-520.
I believe it is the TV-506. You might try tracking down one
of these (or the manual) to see how Kenwood did it.

The '520 finals -- 6146-- will operate at well above 6 meters.
As I recall, the TV-506 used a single 6146, or else a 2E26, and
made only 5 - 10 watts. Whether you could use the '520 tank circuitry
at 6 meters without chopping off the rest of HF is another issue,
and I wouldn't even guess, except that if you have a clean '520
it's too nice a rig to butcher.

R. F. Parts in California (advertises in both CQ and Qst) sells tube sockets and their latest catalog has the sockets and the chimneys for 4-1000-A. Peter Dahl makes a 7.5 v 21 A transformer and it is top quality. That is such a specialized xfmr that there are hardly any like that around. As for the tank coil, you would do best to wind your own from copper tubing. The B&W coils (850 and 852) will nothold up long if there is any impedance mismatch because of the high circulating currents. You will have much greater efficiency if you wind your own. I have been through two B& W tanks and they were made for not more than 1 k.w. INPUT. Now days people want 1.5 kW OUTPUT which means running 2.5 to 3 kw INPUT. Talk about cooking something!

Good luck.

Need to know which is better. I know that class ab-1 is less efficient
but cleaner. Class C is more efficient but dirtier.
What is better? Have an amp project that I am starting.
It is going to be around 200 watts and use 2 transistors in a
push pull format.
Any help apppriciated.

Hi,
I recently purchased a YAESU FT-102 transceiver. What a fantastic piece of equipment! Now I am seriously looking for the optional AM/FM Module that goes in the bottom of the YAESU FT-102. Also looking for the matching remote FV-102DM Digital VFO for the FT-102.

You are correct Dean. Most clubs will recognize a rig as being homebrew
if you put it together. The purpose is to promote experimenting and the
improved understanding that could come from the same.

I also feel that if you made the radio from a schematic and produced
your own boards....then that is homebrew.

In the real world that would include very few hams. For better or worse
most people are the "paint by numbers type".

As Jerry Seinfeld once said , "Not that there is anything wrong with
that" :-)

I don't think it's quite that easy. The AUX position was there to be
able to and one of the WRAC-79 bands, but Kenwood never marketed any kits
to do it. I'm certain that besides a crystal, you need to put in some coils.

Bigger is better, but I use an 8" by .5" rod from a very OLD
radio (1960's) and don't know where to get them that size today.

>
> Could you expand on "shield in a chicken wire" expression you used.

Loose (large opening) Faradays cage. Screen with holes big
enough you can get your thumb through. Wrap around the rod and ground.

>

Yup! Be sure to place a variable capacitor parallel to the
inductive winding. You can find the resonant frequency to set your
turns ratio by injecting an RF signal at the frequency you wish to
center, center the variable capacitor, and wind until the drop across
the tank circuit peaks. Simple. :)

>

You might want to check with Fair Radio as they had some nice 4-1000
fil xfmrs new stock for under 40 dollars on their web site. I bought
one about a month ago and it looks great Triad Magnetek open frame
style and will do either 6.3vac ct or 7.5 vac ct using primary taps

depending on your area, a "handie-talkie" is usually the first choice of newcomers.
it is inexpensive, flexible, and usually let's you directly enter a freqency from
the keypad. a nice touch for starters.

This reminds me of something fun we did when I was teaching high
school electromincs 20 years ago.

You take a colour TV set (preferably a beaten up old one that nobody
wants!!) and you disconnect the deflection coils on the yoke (around
the CRT neck). They are VERY easy to get to!, and then you connect
them to an audio amplifer just as if they were speakers!
The left channel will go to say the horizontal, and the right channel
to the vertical. Then when you play some music or speech over the
stereo, you get all these interesting red green and blue circles
dancing all over the screen. Really makes a great light show and costs
very little. DIfferent sounds produce different patterns.

Great entertainment for $0.00

Also teaches the kids principles about deflection of electron beams
etc. in a manner that grabs their attention readily!

commquart@aol.com eloquently wrote:

::LO and the analog VFO, driving the R2.

cut

: In short, we heard no birdies or other noise covering up weak signals.
: The DDS did have an internal LPF on the output set to 14.3 MHz. The
:DDS was originally intended for another non-ham application, and was
:tunable only by a DTMF keyboard entry, so we could not check operation
:while changing frequency (no continuous tuning). The DDS was enclosed
:in its own metal cabinet, with BNC output.

How many bits does the DDS phase accumulator have? If not known, what is
the frequency step resolution of the DDS?

Your results are intriguing. In any case spurs -45db down would severely
compromise the dynamic range of the receiver, even if none are heard in the
audio. But the dynamic range would probably jump all over the db range due
to the unpredicability of the spurs. Thus one test might show 110db
dynamic range, and yet another frequency show 70db, etc.

An analogous situation is the noise floor of a VCO or VFO fed to a mixer.
If there a high noise floor around the desired freq it shows up in the
receive audio as noise when under strong signal conditions. Hence
"noise-limited" results for some dynamic range tests like in QST. I would
expect analogous "spur limited" dynamic range tests when the DDS is used.

Rob.

3889. Help Needed With Henry Tempo 2002 Amp ..

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-08 00:00:00 UTC
From: daveb@buffnet.net
Message-ID: <5icf7c$ef6$1@buffnet2.buffnet.net>
Source record: 95205

Hi Folks,

I recently acquired a Tempo 2002 Henry Amp. The amp loads perfectly (L4 link inductor) with the safety cage (internal) off. In fact the link is well above the top of the cage when properly loaded.
L4 does not appear to be the OEM part. It was hand formed (poorly) and is physically too large.

A call to Henry didn't help. No replacement part or dimension drawing is available.

Just to confirm what I thought I formed another link which is smaller overall and now loads in a much better position (physically lower). Problem is with the cage back on the situation is better but not quite right.

I'm hoping some kind soul who owns one of these beasts could provide the dimensions (or a photo with the cover off) of L4. I really do not want to run it with the cover off.

Thanks .....

> Any help apppriciated.

Depends upon the application. For AM and SSB, you need a linear amp so
that the sidebands are amplified without distortion. For FM or CW, a
class C amp will suffice.

At any rate, a transistor power amp will require filtering at the output
to control spurious emissions.

>It is going to be around 200 watts and use 2 transistors in a
>push pull format.
>Any help apppriciated.
The answer is NEITHER. *If* you're doing push-pull, you want class B
or possibly class AB-2, which are well suited to push-pull operation.
If you use Class A or C, it would make more sense to use a power
combiner than to try to use a push-pull configuration.

Class B is more efficient than AB-2, which is more efficient than
AB-1, which is more efficient than A. (but AB-2 is less efficient
than class C), but it is likely to introduce harmonics where the
waveform being amplified crosses over zero volts. A skootch of
forward bias on the two stages drops efficiency somewhat (because the
transistors are both conducting when there is no signal), but it
reduces distortion.)That's AB-2.

However, distortion isn't always a bad thing for RF amplifiers. It
depends a lot on what kinds of modulation you want to amplify, because
you can filter out class C harmonics with a really good filter between
the final PA and the antenna. I can't remember which modulation modes
can tolerate non-linear amplification, but reference to the Radio
Amateurs Handbook should give you more than you want to know about it!
:)

Yes, the 1N3305 thru 1N3350 series is the stud mount w/ the 1/4 - 28 thread. Standard polarity is anode to case, and reverse polarity versions are available.

I don't think NES sells direct, and unfortunately I don't know who is the distributor for Wisconsin. Call NES @ their toll-free number to find out.

And you're quite welcome, Jim.

>Dale
>W4OP- another ELNEC user

entire original postings kept.

If you get a package from the grocery store,
and cook it and serve it, was it "heat and serve"
or did you have to mix it up and cook it from raw?

If you made a HW-8 I believe it was Homebrew.
If you made a rig from an ARRL handbook schematic,
That too was homebrew.

If you started with a piece of paper, and a pencil and
designed the whole thing, that was RARE ! ! !

Somebody said something about 55 - gallon oil drums.
Back there just about the time dirt was discovered, we
built duplexers out of coffee cans.

The 2-M dupers were 1 lb cans, and the 6-M dupers
were 3 lb cans. We soldered a nut to the side of the
can and put a tuning wafer inside with a shaft screw
thru the nut on the side of the can.

I believe the plans were found in a magazine at the time.

Don't remember which or when, tho.

Don't give up just because someone else don't know
whatcha talkin' about.

BTW, it may not be tunable, but the hardline duper
mentioned should be more precise from the start.

Go with AB if you want to work SSB or other amplitude varying modes,
class C for FM, FSK, or CW modes.

On Wed, 09 Apr 1997 07:20:54 GMT, archer@netgate.net (Ross Archer)
wrote:

>The answer is NEITHER. *If* you're doing push-pull, you want class B

>combiner than to try to use a push-pull configuration.

I don't understand why you believe that Ross. It makes no difference
in circuit complexity or operation if the amp is A,B, or C . That is
only a bias change.

Class C push pull has been around sinnce the early years of radio, as
has class A.

>Class B is more efficient than AB-2, which is more efficient than
>AB-1, which is more efficient than A.

The 2 designates grid current. The 1 indicates NO grid current.

Neither has anything to due directly with efficiency. Only the
conduction angle and waveshape of PA anode , drain, or collector
current controls efficiency controls efficiency.

Class AB is a conduction angle of less than 360 degrees but more than
180 degrees. Class A is 360 degree conduction angle, while C is
anything less than 180 degrees.

The maximum theoretical efficiencies are:

Class C <100%
Class B <78 %
Class A <50%

So a class AB would be anywhere from zero to just under 78 %
efficiency. The class C would be anywhere from zero to 100%.

Transfer characteristics determine distortion in a RF amplifier, NOT
conduction angle. As a general rule class AB and A amplifiers are
cleaner than lower conduction angle PA's, but that is ONLY a general
rule. There are cases where class C PA's can be cleaner than a class A
PA. Even non-linear curves are OK as long as the curve produces an
even- order response near zero zignal conditions.

Any RF PA will become "dirty" if sauration or a non-linear input vs output power operating point is selected.

>Hi
>Has anyone done it ? Any IDEAS ?
>Thanks in advance de Isaac, 4Z4TL

It was called the TV-506. I've used one at a club station in Drexel
University once. The output power and sensitivity weren't great, so
they followed it with a pream and a power amp.

My suggestion: If you really want sideband on six meters, try the
Ten-Tec kit. There must be a PA driver you can steal from the TS-520
somewhere. If that driver output is anywhere around 14 MHz, you're
set. Just don't try feeding 100 watts in to the Ten-Tec transverter.
It won't work very well for very long.

Assuming a PC compatable there are four comm ports COM1-COM4. However 1 and 3 share the same interrupt line, likewise with 2 and 4. If your modem is put on 4 then 2 will be available for your ham equip interface as long as you dont try to use your modem at the same time. So if your modem is on 1 put it on 3, if on 2 put it on 4. Your mouse is probably on one of the ports also. Best leave the mouse alone as you always need that. Help?

Lou or Annette Hinshaw (aruder@pipeline.com) wrote:
: SHOW ME HOW TO PROTECT IT FROM THIEVES AND YOU GOT A DEAL.
: That was the original intent of my posting. I need to find a way to
: assure that I will not be told (AGAIN!) that "we don't need you."
: after the details are revealed.

Patent it. Or for that matter, just file a patent disclosure
before showing the details to anybody. Be careful about it till
the patent is actually issued. Get people to sign non-disclosure
agreements.

Then--talk with someone who's really competent about it. Be really
willing to listen to the feedback they give you. Be sure you can
demonstrate to them through tests they buy into that your ideas
actually do work. Note that their competence and their approval
of the tests are both critical. Many university communications
engineering professors would fit the bill: relative lack of
commercial interest, open-minded, and competent. Don't think
they are not open-minded just because they disagree with you. And
be willing to pay a consulting fee for their services.

Certainly if you are bright enough to create significant
intellectual property, you are bright enough to protect it. You
aren't the first, and won't be the last. If you approach everyone
like they are a thief, it's not very likely you'll make many
allies.

Even companies like Microsoft aren't immune to thievery, but they
are certainly quite succesful in spite of it; if your invention
involves hardware, it's likely easier to protect than software.

This is not to say I have any confidence in your claims.

You can use a high voltage NPN for that. I have one in my DX-100 and it works well. Mine is NTE2303 TO-220 horizontal output type. A high voltage mosfet might work also. They have those that go up to 800v and beyond.

With the solid state device, key click is much more controllable. I would assume with a mosfet, with its large gate capacitance, a resistor in series with gate would be all you'd need to control click.

Source record: 95228
Cross-posted to: alt.radio.scanner,alt.radio.scanner.uk,rec.radio.amateur.digital.misc,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc,rec.radio.amateur.space,rec.radio.scanner,rec.radio.shortwave,uk.sci.weather

Hello fellow WEFAX FAX SSTV RTTY enthusiasts.

I've just updated by FTV program - current release is 0.98f
Download it from http://www.geocities.com/SiliconValley/2504

For the first time, I have released the software as full-featured
shareware.

FTV brings innovative digital signal processing and analysis techniques to
your multi-media PC. It can be used to receive images from Weather
Satellites and Terrestrial Facsimile Stations, text transmissions from
radio telex services, as well as Amateur Radio FAX, SSTV and RTTY signals.
It can also transmit Amateur Radio FAX and SSTV (Slow Scan Television). No
external hardware, other than a radio, is required, as all the necessary
signal processing is implemented in software.

FTV uses a SoundCard to decode:-
WEFAX weather photos from weather satellites
FAX wirephotos and meteorological maps (Supports FAX transmission)
SSTV pictures in monochrome and colour (Supports SSTV and SSTV COLOUR
transmission)
Baudot text (RTTY)

Here is a run down of soem of its hot features:

(1) It keeps the demodulated signal in memory, so that the signal can be
analysed again at a different keying rate or polarity! Garbage can be
resampled on the fly, which means that minutes of received signals decoded
at the wrong baud rate or keying polarity are recovered, on the fly, while
still receiving.

(2) Keying rate and polarity are analysed automatically - standard baud
rates are automatically set following analysis (assuming you have
calibrated your system as described in the documentation file
'readme.txt').

(3) Tuning oscilloscope available at all times, without loss of copy.

(4) Program works in real time.

Take a look at my web site for futher details, at:
http://www.geocities.com/SiliconValley/2504

What can I say ? Try it, it's free, and may you have as much fun as I am
having...
And, keep me posted... If you have suggestions, you have got to let me

know!

73's from Brian.

Get around that by replacing the yoke with another from a junked set
of the same size. Leave the original yoke connected, but off the CRT.
Put the new yoke on the CRT and connect its windings to the circuit of
your choice.

I saw this in Elementary Electronics some 20 years ago; you may still
find copies at a hamfest; the same publisher also reprinted this
article at least a few dozen times. The article only dealt with the
then-very-common B&W TVs; I think it *should* work with color but I'm
not real sure.

If it does work, another possibility for play would be to connect the
RGB inputs into the CRT board (which are relatively low-voltage) into
the circuits of your choice. Hey, look, Z-Axis modulation in *three*
colors! :)

: >I assume they used the horizontal deflection circuits in the set, and
: >applied the signal to the vertical deflection amplifiers. I would think the
: >bandwidth and the sweep capabilities would be limited.

: The bandwidth is about 6 MHz, and that can be extended to maybe
: 10 MHz without too much work, but the sweep is the real problem.
: You can't deviate very far at all from 15,750 Hz for the horizontal
: deflection because the flyback circuit (which makes HV for the CRT)
: is resonated at that frequency and is an integral part of the horizontal
: deflection system. For a 19 inch set, that gives about 3.26 microseconds
: per inch as the sweep rate. That's pretty fast for the sorts of signals
: an oscilloscope with a vertical bandwidth of only 6 MHz would normally
: observe. It's too fast for most audio work, and ironically it is too
: fast for most TV service work where a deflection factor of 5 mS per
: division or 20 uS per division would most commonly be used to observe
: the vertical and horziontal waveforms respectively.

6MHz bandwidth for the vertical deflection??? Yeah, rrrright. Maybe for
the video, which is intensity modulation, but I'd have a heck of a time
getting much info out of looking at an intensity-modulated straight line.

These days, the way I'd turn a TV set into a scope is to digitize the
signal of interest and store it in memory and generate a raster-scan
image of it. You could probably make a 20MHz scope this way from not
very many parts. You could use something like an old Amiga computer
to handle the video for you, since it's capable of outputting
interlaced NTSC-scan-rate signals; or if you don't need too much
vertical resolution, something like a Commodore 64 could do.

Cheers,
Tom

hi george
wild guess is the finals are shorted. I have never had my 440 overheat except sending weafax. if the heat sinks get warm now,and the fan on the ps50 runs.
check the power supply current and voltage.if it is above an amp on recieve there is a short.

A Helical antenna is a circularly polarized antenna.

Circular polarization comes in too "senses" Clockwise (CW) and Anti-Clockwise (CCW).

A circularly polarized antenna will respond to signals of ANY polarization - except circularly polaized signals having the oposite sense.

The loss between linear (horiz. or vert.) and circular is 3 dB (only 1/2 'S' unit).

Linearly polarized singals frequently rotate form vert. to horiz. - I have measured as much as 235 deg. or rotation at 145 MHz.

Therefor: At times a helical antenna will work better for receiving signals that were transmitted with linear polarization.

From: Jetleb@netcom.ca
Message-ID: <334C81E7.31E0@netcom.ca>
Source record: 95239

If anyone is interested, I have built a home-brew keyer (and key for that matter) that I used for my 5WPM test. It was done under windows95, but can be converted to other formats. The unit is based on a microcontroller and doesn't have any real bells and whistles, but it does automatically adapt to the type of key you are using and whether you are right or left handed. I could have done more with it (I didn't use 6 I/O pins), but I only had a week to go before my test and I didn't have a key or keyer, so I was desparate and in a rush. It costs about $15 to $20 to build. Give me a shout if you are interested.

Just to warn anyone interested; the file is about 5Mb long, including all embedded photos and autosketch drawings. It's about 2.4Mb long in ZIP format. I can convert it to other formats (Win3.1, MSDOS text file, etc), but you might have to sacrifice the pictures and/or diagrams.

yes you can but it will have to be done with surface mount parts. but
that is not the biggest problem. If you use one of the rs-232 lines for
powering the device make sure not to exceed the amount of current that the
line can provide safely. Also, if you choose to power the thing off the
rs-232 line use a small bridge rectifier before the actual device. This
will keep the positive positive and the negative negative dispite the level
on the pin you use

a less involved solution would be to enable the disabled port under a
new
address. com4 to be precise. while this does not allow simultaneous
use
of com2 and com4, the likelyhood of this need is low. either enable the
port from the 1.motherboard jumper, 2.card jumper, 3.cmos setting.
this works well if you do NOT plan to use the com4 port and the modem on
com2 at the same time.
com1=3f8
com2=2f8
com3=3e8
com4=2e8
incase the jumpers specify hex addresses rather than logical port names

I second this approach... I am running a serial mouse on com1, modem on com2, and the second (DB-25) as com 4. W95 shows conflict, but I just don't use the modem while I am using the serial port. Did a similar thing when I was running W3.1 on the old 486 - Except the int modem was com 4 and the available serial prot was com2.

That won't work, either. The command line should read:
subscribe glowbugs your_email_address
(you need to state the listname).

For those not aware, Glowbugs is an email list devoted to homebrewing
with tubes. It's an active list that has regenerated quite an interest
in building. I think the book on regen receivers has been rewritten
due to the activity on there!

Ed,

The K2TL homepage: http://members.aol.com/jkktl/ham.htm has the
program WxSat which uses your soundcard to decode the Polar Orbiters
and Meteosats then displays the WAV file as a BMP. An excellent
compilation of SSTV programs is found at http://www.qsl.net/n9ngf/
Some of the programs are DOS and some are Win95. There are
descriptions and shareware to be downloaded directly from the site.
I'd have to do a search to find some other sources and my
ISP server is running s..l..ooo..ww.. tonight. Just search using
Webcrawler or Yahoo to find SSTV software, RTTY software, and
Wxsat links.

>
> Thanks in advance. Petedash/dot ratio=3. spacing between elements (dots &dashes)= 1 dot
space.
Spacing between characters (letters, numbers etc)= 3 dots=a dash.
Spacing between words= 5 dots. When I say 5 dots I mean 5dot lengths w/
NO space between. 10 WPM consists of (theoretically) ten 5 character
words.
With that said, why reinvent the wheel. This exercise was accomplished
with discrete TTL as early as 1975 by Petit in QST, and hundreds of
times since. Even the ability to track different speeds is an elemental
exercise.

Lots of part # suggestions in other replies. Consider surface mount types if you can, as they'll be easier to use at high frequencies. You might also consider adding a DC 'tickler' bias of the diode through a suitable resistor and/or inductor. This can make the detector more sensitive. You may need to experiment with temp. comp. on the bias.

3937. HOW TO?? - VHF VCO Circuit -- HELP!

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-10 00:00:00 UTC
From: bryan@conquest.co.nz
Message-ID: <5iij03$s1$1@fep4.clear.net.nz>
Source record: 95105

Hi there. Thanks for taking the time to read this.

I have been trying to create a simple VHF VCO for a PLL circuit which will cover a decent bandwidth.

So far the best I can do is around 15MHz (say from 142MHz to 157 MHz). I SHOULD be able to do a LOT better.

The circuit I have been trying is a colpits oscilator using a parallel LC resonant approach. I am using BB204 varactor diodes. The biggerst problem appears to be that the oscilator quit at around 2 thirds capacatance - this is only about 15 to 20pf !

Of course I can make the osc. run at that level but only by increasing other L's or C's which brings the whole thing down the band - I still don't get more that 20 MHz band width out of the thing....

I am at the point of giving up!

Does anyone have a circuit which they knows works?? The frquency range of interest is 130 to 160MHz... The wider the better.

Any help or directions to references much appreciated.

73 de ZL1HIT (Bryan)

P.S: Please respond (at least with Cc) to my email address as I don't get a chance to check the newsgroups very often. Thanks.

3938. List Of Stamp Applications [970410]

```
Since the L.O.S.A is getting bigger I only post the index of
applications to the Usenet groups and you can download the
complete L.O.S.A from the following places...

WWW:

http://www.hth.com/losa.htm

FTP:

ftp://ftp.parallaxinc.com/pub/text/losa.txt

1.0 Whats is L.O.S.A all about ?
--------------------------------

I started to compile L.O.S.A because I know there are lots of great
ideas and many problems that are solved with the BASIC Stamp and the
main purpose of this list is to get an idea of what other people are
using their BASIC Stamps for and maybe get some inspiration or hints.

1.1 How can I contribute to this list ?
---------------------------------------

If you have done something (big or small) with the BASIC Stamp that
you are willing to tell others please use the form given below and
write a short description, nothing fancy is needed just a simple
explanation. If you have source code to share that's even better but
it's not necessary.

Visit the following Web site and fill in the contribution form...

Newer 'lytics are getting smaller and smaller. These sound like they might be for photo-flash use. If you can see the top of the can and it has a cross scored into it, then it vents up. Any hole in the 'rubber' on the bottom may mean that it vents down.

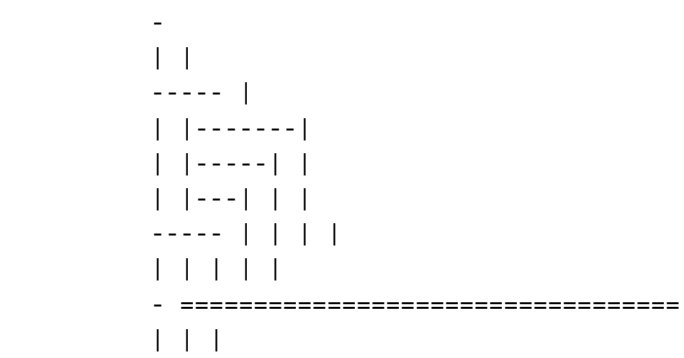
Somewhat surprisingly, I am not able to find a source for DB15 High Density connectors, like what are used for VGA connectors, that can be soldered onto a PCB with right angle pins.



Any help in finding a DB15 High Density that can be connected to a PCB at right angles would be much appreciated.

Thanks, Henry

To all of you radio amateurs out there ! A plea for help from
someone bogged down at the moment.
I have obtained the wxsat software which works perfectly with
prepared .wav or .bmp files. I have also obtained a sound card (Idema
sound card series Schubert which is a 16bit ES1868 card) This has been
set up with port 220H, interrupt 10 [to avoid clashes with network card
set to 5] and DMA 1. It is set for wave file processing at 11.025kHz,
mono, 8 bit
No matter how I try I cannot produce a .wav file from the system
even though the input (into the audio plug on the card) produces sound
from the monitor speakers. I can also play CD's via the CD player,
but....NO .wav file at all. I have tried live signals, and recorded
signals all to no avail. I have even tried to contact ESS technologies
in the States by e-mail but have had the message returned with this
address unknown. So at the moment I am having to suck my thumb, mainly
since I am neither a radio amateur or a computer "literate". The
setting up of the system was done for me as I am essentially an amateur
climatologist (retired).
So, can any of you boffins out there throw any light on my
problems and even suggest what I can do to get a .wav signal. Have I
got a duff sound card ??
Thanks for any help or guidance,

What happens when you tap, ie. make a direct connection to the center conductor of a quarter wave coaxial resonator? How do you model the result in PSPICE given a transmission line element? Would the tap be just an ideal transformer? If so, how would you determine the turns ratio from the physical tap location?

Thanks for considering these questions.
Brad

If the transmission line model does what you want it to when you
use it as an un-tapped quarter wave resonator, (big if), then all you
have to do to make a tapped resonator is to put two transmission lines in
series with the tap being between the two. The total length of the two
being the same as the un-tapped resonator and the ratio of the two
setting the tapped percentage.

I am going to need to capture the printer output of a P.C. with another P.C. Somebody suggested a LapLink cable which sounds like an excellent idea on the surface. What is in one of these cables? I understand that the old P.C. parallel ports only had 4 inputs since they weren't really designed to ever receive signals except for the strobes.

Does the LapLink cable have some logic in it that shifts four bits over so that one can receive bytes in two-nibble operations or exactly what is happening? I will have control over the software on the receiving P.C., but the sender will have to think it is sending to a printer. It's a lo-o-ong story.

One good thing is that I don't need a bidirectional data path. The data will flow in one direction only.

Chop the resonator into two pieces at the tap point. attach the feed
at that point. The transmission line model takes care of the rest.

Aha! But there is such a thing. In the October 1938 issue of
Electronics, there is an article by Stanford Goldman entitled "A Shielded
Loop for Noise Reduction in Broadcast Reception" (pp. 20-22). This is an
electic field antenna (ferrites were yet to be used in common practice),
wound on a wooden frame inside a cylinder covered with what looks like
either window screen or hardware cloth. There's also one in which the
antenna loop is between two concentric metal screens. This is an inter-
esting article for those of you engaged in this thread.

I gotta go.

I made four or five of these TV oscilloscopes in high school. Normally,
I would disconnect
the two horizontal wires to the yoke and tape them off (so they're not
connected to
anything). Then I'd disconnect the vertical wires going to the yoke and
connect them
to the horizontal winding of the yoke. Then I'd connect my stereo to
the vertical
winding of the yoke. The TV's vertical control now controls the sweep
rate. The
sweep was absolutely perfect for viewing speech and music :-)

Of all the TV's I converted, only one needed an extra yoke to connect the horizontal
output to. Of the other converted TV's, none of them "smoked." In fact, I still use
one of the converted TV's in the garage as a regular TV. Of course, I had to convert
it back :-)

Good luck!! I've made a couple, and tho they work fine under good conditions, NOTHING beats the human brain and ear for picking that tone out of the noise
and discrimanating between tones. You can PPL your input circuit, AGC your lervels, but performance still comes nowhere a trained person. Learn and practice your code.

If you have DOS 6.2, type "help interlnk". The notes section has the
pinouts for a laplink cable. It's just wire. There was a program
called
Flying Dutchman. Their cable had 100 ohm resistors at the source end
of each signal. Should work over longer distances than the standard
laplink cable.

The laplink software splits the
bytes up to nibbles then reassembles it at the other end.
Sounds like your problem of sending a file with a print command without
intervention is a lot more complicated.

There are shareware programs that can capture printer output to a file,
but you'd have to manually send the file.
Can't help much without much more detail of the problem.

snip/hack

You might (Lou or Annette) check Don Lancasters books or home page for some interesting reading on how to control your property and the steps to develop and market it. It shouldn't be a really big deal to be able to devise a black box rf modulator/antenna, followed by an rx demodulator/antenna, and let the folks look at the spectrum with an analyzer while piping some music or audio in, and looking at the resultant demodulated audio out.,,, or even if you used a wire link, let them put a narrow bandpass filter at the freq of your choice in the data link and pump their audio thru the unit and look at the distortion figgures. At least, while not the definitive proof of function,,, it'd work good enough to get you in the door you're looking for.

Henry,

Mouser Electronics seams to have what your'e after. On page 124 of
their feb '97 cat, they show right angle pcb D-sub (plugs and
receptacles, $1-3 range) and many pages of other type. D'be surprise
you wouldn't find what you need there.

These people are very cooperative and offer a heck of a good service,
even for us, north of the border.

(800)346-6873
open 7am-9pm week days
8am-5pm weekends

http://www.mouser.com
email sales@mouser.com

Good luck, H.C.

>It is going to be around 200 watts and use 2 transistors in a
>push pull format.
>Any help apppriciated.

The big question is will this amp be for linear service. AB1 can be
linear, class C cannot. Class C is useful for CW or FM and in the case
where the final is modulated in AM service. It need not be dirtier if
well designed. A well designed class AB1 amp will work well in linear
operation for any mode although as you say efficiency will be less.

:be appreciated.
:
: Thanks, Greg K3EWZ

Siliconix data book says that it is a single pole single throw analog
switch, in other words an enhancement mode single gate DMOS fet. 1-source
2-drain 3-gate
4-substrate, 1 starting c.c. on bottom view of can from tab.

Rdson = 45ohm, Vbrds = 20v, ton max = 2ns, WOW, thats fast!!!

I have a source here for SD305's, another very old Signetics part from
early 70's. I've never been able to find it in any old databooks. If you
get any databooks and see it, please email me. What I know:

SD305 is an enhancement mode dual gate MOSFET. Thus no drain-source
current flows until both gates are biased positive to several volts, unlike
normal dual gate mosfets where current flows all the time unless gates
biased negative.

I figured they used these as logic gates, but I've used them as commutation
mixers.

>does anybody know if a helical antenna will pick up a
>vert. transmitted signal,if so how effective?
>jerry
>
There are two types of helical antenna. The one commonly used
at microwaves is the axial mode helix, which radiates/recieves in
the direction of the helix axis, and has either left
or right hand circular polarisation, and either sense will pick up
a vertical transmission with -3dB loss compared with a
circular polarised transmission. Of course, if your helical
antenna has a gain of 18dB, you still have 15dB gain effective.
They are indeed useful when the plane of polarisation is unknown
since it does not matter (the gain is invariant with rotation about
the axis in the ideal case, in practice it may vary due to slight non
circularity of polarisation). Polarisation shifts can happen
in transmission through the ionosphere, or through built-up areas due to
reflection and diffraction, or earth-space due to uncontrolled orientation
of satellites or space vehicles; hence the helical circular polarised
antenna is common in space applications.
The other type is the normal mode helix. This is used at lower
frequencies, when the radiation is normal to the axis. This type
is commonly used in compact "rubber duck" antenna for hand portables
and vehicles; the helix reduces the length required for quarter or
higher multiples of quarter wave resonance. Your original
message did not specify which type of helical antenna. If the
normal mode antenna, this is linearly polarised and should be
oriented with the axis aligned with the vertical in the same way
you would use a whip or dipole.

3976. Ideas For Panel Labeling?

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-11 00:00:00 UTC
From: donrm@sr.hp.com
Message-ID: <5im0m2$st0@canyon.sr.hp.com>
Source record: 95056

Anyone have any new ideas on lettering/labeling the panels of your home-brew projects? So far, I've tried the following:

1. Dry transfer (Datak, Letraset, etc) with clear Krylon overcoat. Disadvantage is they can be scratched off, take a lot of patience, and the medium has a guaranteed shelf life only about five years.

2. Labeling tape (ugh!), but clear KROY labeling tape doesn't look too bad. Great for a one-time kluge. KROY Type 80 has a variety of fonts available and can be mixed on same label. Have to find someone with the labeling machine, however as it's too expensive for hobby use.

3. 3M (Scotch) system - lay labeling artwork over photosensitized film or thin (almost foil-like) anodized sheet. Run thru ozalid machine; develop. Look great, several colors, but too expensive.

4. Wordprocessor/overhead foil/laser printer. Works good, variety only limited by your imagination (graphics, etc.) but requires some experimentation and you have to have the equipment. (laser printer, computer, software, etc.) Disadvantage is how to affix the foil to the panel so it doesn't show adhesions to the panel surface.

5. Silkscreen - messy and might not be worth a 'one-shot' project; you can get very professional results and wear resistance.

6. I once tried a variation of #3 above. I spread negative photoresist on an anodized panel, exposed it to my artwork film, developed the panel and etched the lettering thru the developed photoresist "windows" with NaOH (solution of Drano, actually). Wound up with a black anodized panel with aluminum colored lettering. Looked great, but a lot of work.

7. Leroy lettering with india ink on a clean panel; coat with clear Krylon. Lots of fonts available, but haven't seen a Leroy lettering set in 20 years.

So...anyone have any other favorite method/idea?

>esting article for those of you engaged in this thread.

But the problem is the shield does not shield the antenna from time
varying electric fields. If it did, the antenna would receive no
signals at all.

The shield can modify direct coupling via capacitance, but that effect
is almost always so small with a small loop antenna the shield is a
waste of time.

The only case I can think of where a shield would improve things is
the case of a small loop mounted very near an undesired source of
strong electric fields, and where the loop itself is not symmetrically
placed, or where the amplifier the loop drives is sensitive to common
mode high impedance sources.

In most cases the "Faraday shield" just physically holds the antenna
in place. :-)

The shield attenuates (reduces greatly) the electrostatic component of the EM wave. The magnetic component travels freely through the cage. Most noise signals are stronger in electrostatic than magnetic due to how they are generated. Broadcast signals typically have much higher magnetic component since they are launched off a resonant "tuned" radiating element (antenna) while the "noise" from your fluorescent lamp, fan motor, computer, etc., is launched off an untuned, non-resonant radiating element (power cord, wires, etc.)

Shielded magnetic antennas will also nul strong stations in opposite polarity to where it is turned, thus you can blank a station on the same frequency (jammer) that happens to be in a different location geographically from the source you wish to receive. This is the upside, the downside is that shielded magnetic antennas are highly directional, and unless you point it in the direction the signal is coming from, it won't receive the signal at all. With a partial Faraday shield, and by adding a bit of a whip antenna to the device, you can give it less directional characteristics to "find" your station by adjusting until the signal outweighs the noise (best of both worlds). This is how I use mine. I have a "tail" outside the Faraday shield which allows all signals into the resonant loopstick tank so I can find (albeit weakly) the signal I want, then zero in on it, thus having the magnetically induced signal outweigh any noise the "whip" will pull in (high signal to low noise ratio).

A quick and reasonably (though not perfect) method I've used on some quick projects.. is to print the labels on a laser printer, stick them in place (maybe with a dab of super-glue), then cover the whole panel with see-through shipping tape. Fast, easy, and looks fairly good. You could, in theory, print on a dot-matrix too, though it wouldn't look quite as good.

Neither of these solutions accounts for the coupling between the lower and
upper parts of the resonator. I don't have a ready solution, but I don't
think two transmission lines in series with the tap between will be an
accurate representation either.

The term "long" in long wire antenna usually refers to being long in terms of a half wave length. (Refs: Radio Handbook, 20th edition, pp 28-2 to 28-7 and The ARRL Antenna Book, 13th edition, Chapter 5, "Long Wire Antennas").

These references show several different forms of long wire antennas and point out that they exhibit gain over a dipole and often seem more effective in reception than yagi style beams according to users.

I've used several random length end fed wires over the years both for receiving and transmitting but I've never used any of the long wire forms as I've never had the space.

So as you can see if you check the literature, there are reasons for specifying a difference between a random length wire and a long wire.

I recall studying a few published circuits years ago that sampled
(rather than digitized) repetitive signals and then raster-scanned
them for display. I never built one because the concept seemed too
limited for the effort involved. One such design was intended as a
science fair project.

I'm not convinced that there is any coupling between the top and
bottom that doesn't pass through the middle. If that's the case, then
two sections in series *should* show all the coupling effects needed.

I'll try some virtual (simulated) experiments and report back.

Burt Fisher, world renowned crap bag, Clinton lover, is at it
again. Burt, how about siting a source for your article? I know
you didn't write it all yourself. Fact is, that copyrighted
material is not supposed to be modified and you are supposed to
cite the source!

As far as LMDS, it operates in 28-30 GHz range. It works in
full rain and it has been working in Brighton Beach NY for
the last 5 years as a pilot. I worked on it for 4 years and
they do not need towers, rooftops work fine! 49 channels
in 20 MHz HDTV channels. Recieve antenna is a 6" square flat
panel. See Cellularvision.com for more details.

As far as seizing ham towers, who is kidding who? There
would be nothing of the sort. I feel like Burt might have
edited that in there. There would be no seizure.
Why add to the article Burt? Does it serve your purpose?
Your purpose was to make it sound like they are coming for
all amateur spectrum. Not yet! The fact about towers and
zoning is something I have first hand experience in. I have
built over 100 towers throughout the Northeast. You can
still construct them, but you might have to allow co-location
which is when several carriers locate on one tower.

Burt, you really are scum, just like that scum that lives
in the Whitehouse. No wonder why you would put up a picture
posing with him on your webpage! You are both twisted liars!

To many of those who have replied to this I have a question :-

What do you do if you have the following requirements:-

1. Serial Mouse
2. Internal modem card
3. External packet TNC
4. Serial communications to your transceiver.

I have the first 3 already but cannot leave the packet TNC operating
when I log onto the internet (an iritation if I am logging the DX
cluster) but how do I get the PC to link to my transceiver as well?

Darn, I missed that article. I was too young back then to
be able to read. ;) In fact, it came out a year before my MOTHER was
born! :) How the hell did you find this? You routinely read OLD
magazines? Actually, the concept is sound, I'm not suprised that I
am not the only one to come up with the idea. Now I wonder how I am
going to find such an old magazine? Libraries microfilm magazines, but
do they have them going back that far? Somehow I don't think so.....sq

(now the question arises, why did the idea die into obscurity? It is
not like electrical noise got LESS as time marched forward!)

To the best of my knowledge the 9612 can emulate POCSAG pager formats but no others. There are a lot of pagers around. I know that Communications Specialists has a hoard of 450 mHz tone and voice pagers for about $30 in nearly new condition. For a couple of dollars extra they'll include a new battery and charger.

I have 22 and 24 AWG teflon insulated ,silver plated, stranded hookup wire in 500' metal and 1000'plastic spools.

I also have assortments of 22 and 24 AWG stranded,silver plated,teflon insulated wire.

10(50') spools or total of 500' of 22 and 24 gauge silver plated, stranded TFE insulated wire in 10 different colors.
This is called a "superpak" and I include 5 feet of TFE insulated mini coax.

Cost including shipping (continental US)

superpak $44 (by 2 day mail)
500' spools $25 (shipping included)
1000' spools $48 (shipping included)

Note on larger quantities that is 4 cents per foot for the wire !

If interested contact me at jskalski@acsu.buffalo.edu

One good place for details on software implementations for cw decoding
is as RSGB book called Amateur Radio Software. I believe that this is
available through the ARRL. A few notes:
1. The book deals with actual code in basic (!) and machine language for
various compuers circa 1985 (Vic20, C64 class machines). The machine
resources may be similar enough to microcontrollers that code translation
may be all that is needed.
2. Developing a machine-language program for this kind of realtime process is
a good way to start developing the necessary skills for realtime signal analysis
and decoding in general regardless of whether you read cw by ear (a skill which
I encourage).
3. The modern discipline of Digital Signal Analysis is not represented in the
book.

Forgive my ignorance, but aside from the waves flowing up and down the line (in the ideal case) is there any other coupling between the transmission lines?

When you find one of those books look for a design known as a "discone" antenna. I have not used one, but they are supposed to be very "broadbanded".. meaning they will cover several octaves. This seems to be what you want. You want to cover the low vhf to the upper uhf spectrum. By the way.. FM is popular at these higher frequencies, but any mode will work there (and does).

Antennas are possibly the commonly homebrewed ham equipment. Welcome to ham radio and I hope you enjoy it for years to come.

Pete,

You have some direction already, so I'll just caution about those
"timing" issues. The big trick to having a machine copy the code as sent
by a human fist is that the human fist varies its timing!! Those timinbg
specs are tagets that only machines can hit consistently. Maybe *YOU*
can be the first to solve this problem. Best of luck to you.

> terms of a half wave length. (Refs: Radio Handbook, 20th edition, pp
> 28-2 to 28-7 and The ARRL Antenna Book, 13th edition, Chapter 5, "Long
> Wire Antennas").

Does this mean that you must either add wire or remove wire as
you change bands? ;) As I said, there isn't always that much of a
difference. I don't consider my antenna to be a random length antenna,
it is on the long side of my house, and is cut to half wavelength for
the 30 meter band (10 Mhz). The longwire is 48.5 feet long, therefore
it is a longwire for the 30 meter band, and a random wire for all other
bands.

> I've used several random length end fed wires over the years both for
> receiving and transmitting but I've never used any of the long wire
> forms as I've never had the space.

I think you have! :) You just didn't use them at the right
frequency. All random wire antennas are longwires if you find the
right spot on your all-band radio. ;) Like I said, there isn't much
of a difference.

> So as you can see if you check the literature, there are reasons for
> specifying a difference between a random length wire and a long wire.

As I hope you can see there are reasons for specifying frequency
as even a "1 foot chunk of wire" is a longwire for 486 Mhz.....sq

It's hardly new, it's not fancy, but it's cheap. I hand write labels on small strips of paper (4-5mm wide). Then I use 12mm wide clear adhesive tape to stick them to the front panel. When stuck on a smooth surface, the result can last for years.

If two separate lines in series is not an accurate representation, that would imply that there's some longitudinal coupling between the upper and lower parts of a single TEM-mode resonator - which is a contradiction in terms.

Excuse the convoluted logic, but I beleieve it means that the model with two lines in series is essentially correct. There will be some fringing fields at the tap point, but I don't think those are important.

>radiating element (power cord, wires, etc.)

This is not quite accurate, since in the far field (as with the
broadcast transmitter) the relationship between the electric field E
and the magnetic field H is constant

E
--- = Z0 = 120 pi = 377 ohms
H

This is true in the _far_ field regardless the signal was radiated by
a resonant electric dipole, from a random wire or even from a magnetic
loop.

However in the near field (usually much less than a wavelength from
the _noise_ source), the relation between the electric and magnetic
field is much more complex and depends of the type of the noise
source. In this case you might benefit from antennas that pick up
predominately either field. However, if you are in the far field from
the noise source (say, more than a wavelength) the relationship
between the E and H fields is again 377 ohms and there is no benefit
from using an antenna that predominately picks up only the other field
(directivity is a separate issue).

On LF and MF there can be benefits for using a magnetic loop, since
there can be quite a lot of noise sources within the near field. On HF
and VHF the near field is so small that there simply are not room for
a lot of noise sources :-)

>radiating element (power cord, wires, etc.)

There is *no* electrostatic component to an electromagnetic wave. The electric and magnetic field components of the EM wave are *dynamic*, and intimately coupled to each other. Bill Sabin did a very good explanation of this in another post. You can't have an EM wave without both the electric and the magnetic field. The energy of the wave is transferred back and forth between the electric and magnetic field components of the wave continously because one continuously generates the other as they travel through space. That's what allows an EM wave to propagate through space. And since energy must be conserved, the electric and magnetic field components *must* be of equal strength (though at different times as the energy oscillates back and forth between the electric and magnetic field vectors). If you attenuate *one* field vector, you attenuate the other as well because the total wave only has one energy.

The only time this is not exactly true is in the *near* field of the radiating source. In the near field, less than 5 wavelengths from the source, the EM field hasn't fully established, and the signal can be treated as partially separate electric and magnetic induction fields. And *those* fields don't have to be of equal strength. That's the case for noise generated *very* near the receiving antenna.

A *partial* shield can then have some effect in differentiating the fields from far sources as compared to near sources. But if the shielding is *complete* for either field, no EM signal will be received. That's why the shielded loop antenna must have a *break* in the shield.

> Shielded magnetic antennas will also nul strong stations in
>opposite polarity to where it is turned, thus you can blank a station on
>the same frequency (jammer) that happens to be in a different location
>geographically from the source you wish to receive. This is the upside,
>the downside is that shielded magnetic antennas are highly directional,
>and unless you point it in the direction the signal is coming from, it
>won't receive the signal at all.

Well, the idea is basically right, but your terminology is wrong. It
is the pattern of the antenna which results in both the null and
the peak. It has nothing to do with signal *polarity*. That's a separate
issue. And the shield has no effect on pattern, so this directionality
exists whether the loop is shielded or not.

>With a partial Faraday shield, and by
>adding a bit of a whip antenna to the device, you can give it less
>directional characteristics to "find" your station by adjusting until
>the signal outweighs the noise (best of both worlds). This is how I
>use mine. I have a "tail" outside the Faraday shield which allows all
>signals into the resonant loopstick tank so I can find (albeit weakly)
>the signal I want, then zero in on it, thus having the magnetically
>induced signal outweigh any noise the "whip" will pull in (high signal
>to low noise ratio).

Actually, what a loop (shielded or not) and whip do (when properly
combined) is change the antenna pattern from bidirectional to cardioid,
IE sharply unidirectional. That will reject noise and interference from
all directions except the signal direction. This will have the effect of
improving the SNR of the desired signal. Improperly combined, the two
antennas will lose directionality, and *degrade* the SNR of the received
signal.

Note that the whip and loop must be physically small with respect
to a wavelength for this to work. If they grow to be an appreciable
fraction of a wavelength, then polarity raises its ugly head as an
issue which must also be considered. Polarity can be exploited for
other things, such as diversity reception, but it will have the effect
of degrading the cardioid pattern of a loop and whip combination.

I work for Lockheed Martin here in Canada...
When we build "one off" type equipment
we use Fascal 700 media (clear,sticky on back,with backing
you peel off)
we put it throught the HP plotter using drafting permanent
water based pens (several colours).
After the stuff dries...about 30 seconds..
Peel and apply to surface (trick here)
Use windex on surface and on back of peeled off media
(on the sticky side only), don't get it on the ink side.
This gives you a chance to move it around a bit for final
location.
Then roll out all the water and Windex carefully with a
rubber roller like they use to roll down arborite.
After it completely dries...24 hrs
Spray on Acrylic laquer...two coats don't let it run.
Use this as a drilling template after it's all dry!
Works great...looks VERY professional.
Use as Many colours as you want.
We use black for all the control points with little
crosses where we are going to drill, and BIG Blue lettering
because it stands out nicely.
This all comes from your CAD prog by the way.
You can even do diagonals etc.
Hope this helps...

This is an excellent method able to make very professional looking
panels. Etching can be done with the same materials as you are using
for the PCBs.
In the past some companies did make panels this way (some may still
do it!) Conversely, I have had silk screened panels on expensive stuff
and the wear and tear eventually wore off the markings so there was no
idea what the setting of a knob was. An etched panels is likely to
outlast all of us and may get battered but it will remain easy to read.

It is easy to fill the etched lettering neatly with ordinary colored
paint, using different colors for different functional groupings. Nice
effects can be achieved by various methods of preparing an aluminum
panel, by scratch brushing, sanding only in a single direction, or
etching overall before beginning the patterning. One precaution is
keeping the metal rather smooth (only FINE scratches) as the
photoresist may not flow to the bottom of a scratch; you then get an
ugly defect.
(One trick, lighjt sanding AFTER etching in the lettering.)

Ferric cloride works well on Al or brass. I do not know about the
ammonium persulphate.

Bob

Some of the newer modems also permit you to select other IRQs so you can run the modem and the serial port at the same time if desired. You can also purchase serial cards that permit selection of non-standard IRQs. Just be sure your software can also use the desired IRQ.

FOR SALE: Tubes, test equipment, radios including Hallicrafters, Hammarlund, and Philco. Other older tube type radios and radio related publications. Schematics for many older radios just $1. Tube Manuals, Tube Substitution books, Service Manuals, QST magazines, much more from the 30's, 40's, 50's, 60's. Now over 1550 different tube types in stock - Contact Rog42@aol.com and ask for an E-mail copy of my latest offerings on RADIO list - #322-T.

4028. Lithium ion batteries

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-12 00:00:00 UTC
From: w7el@teleport.com
Message-ID: <5iohe4lqp1@nadine.teleport.com>
Source record: 95090

The rechargeable lithium ion battery pack for my notebook computer just went toes-up. The multi-chip smart charger circuitry seems to have gone west, but the battery capacity was pretty badly diminished before it went so it's not worthwhile for me to mess with. But I may be able to salvage some of the cells.

Does anyone know the charging requirements for these beasties? Can a person get by at constant-current or constant-voltage charging, or are they fussy and require special charging circuitry like NiMH and rechargeable alkalines? I don't need an optimum method (since as they are, thery're no good to me anyway), but would like some general info if anyone has any.

Thanks,

Roy Lewallen, W7EL

4029. Audio/electronics for sale

For sale only:

Pro-Audio recording gear:
British-made "ACES"-brand 24-track 2" recorder with remote, 15/30 ips with vari-speed, sold new for $19,000.00. Also ACES 32-input in-line mixer, 24 groups, 5-band switchable EQ, 5 sends per channel, extensive routing options, patchbay, etc., sold new for $13,500.00. All manuals, wiring harnesses, and lots of spare parts included. Both units are one-owner. I'll sell both for $10,000.00.

For sale or trade:

PATCH BAYS:
19" rack-mount patch-bays, with heavy-duty long-frame mil-spec Switchcraft/ADC 1/4" jacks. Front panel is black phenolic with designation strips, attached to a metal reinforcing frame. Jacks are switching type, and may be wired in a variety of ways such as normaled, semi-normaled, etc. They are wired to a "punch-block" which is mounted on the back of the frame, and connections may be made to the punch-block, or directly to the jacks. I have:
Quantity: 3 Number of jacks: 48 Approx. list price: $150.00
I sell these for $40.00
Quantity: 4 Number of jacks: 72 Approx. list price: $60.00
I sell these for $60.00
Quantity: 3 Number of jacks: 96 Approx. list price: $250.00
I sell these for $80.00

I also have:
POWER SUPPLIES
These are "Sola" brand 117VAC in, 15VDC out bi-polar power supplies, highly filtered and regulated, PC-board mount (but easily adapted), and were used in medical heart-monitoring equipment. You can find them listed in the Allied Electronics catalog. I have:
Quantity: 4 SOLA#84-15-2135 Rated at: 350MA
Allied price: $220.00
I'd like $20.00 each
Quantity: 7 SOLA#84-15-2120 Rated at: 200MA
Allied price: $154.00
I'd like $15.00 each

I also have 2 Tektronix Model 620 X-Y display monitors, with 10X12 cm screens, suitable for analog display data such as ultrasonic detection systems, volume & vibration analysis, auger probes, and biophysical systems as well as computer and data transmission systems. I don't know what they cost new, but they are real nice, and I'd let them go cheap.

Make an offer--I'll horse trade!!

Phil it sounds like you have an IRC problem. It is possible that the
TNC and modem are on the same IRC. This can be checked from within
Windows or several diagnostic other programs.

I have the following - Comm 1 -- IRQ 4 = -- Mouse
Comm 2 -- IRQ 5 = -- TNC
Comm 3 -- IRQ 3 = -- Wx data via VHF
Comm 4 -- IRQ 4 = -- External Modem

I am not sure about the internal modem but it must opeate with IRC as
do other deveices. Check and see what they are and are working
together.

Hope this is some help.

Sorry about typo Comm 4 should read IRQ 9. It is a popular
misconception Comm ports MUST share the same IRQs. Even many of the
books on modems/computers will tell you this. It took me a month + to
finally get the above set up working. Check your cards for the
ability to set IRQs other than the standard setup. Most external
modems will operate with any IRQ -- as far as I know.

Get right up next to a high power radiating element and say that!
;) I'm sure there are a few hams who are reading this and smiling right
now. :) EM waves contain both an electrical and magnetic wave component
while noise contains a higher electrostatic component as it is closer
to the receiver than the transmitter half-way around the world. The idea
is to block this electrostatic component from the noise.

> The
> electric and magnetic field components of the EM wave are *dynamic*, and
> intimately coupled to each other. Bill Sabin did a very good explanation
> of this in another post. You can't have an EM wave without both the electric
> and the magnetic field.

This is true, but the faradays shielding is to block all of the
electrostatic, much of the electroinductive and none of the
magnetoinductive components of the electromagnetic wave. This achieves
a reduction in the overall noise level by selection.

> The only time this is not exactly true is in the *near* field of the
> radiating source. In the near field, less than 5 wavelengths from the
> source, the EM field hasn't fully established, and the signal can be
> treated as partially separate electric and magnetic induction fields.

As I was saying, the transmitter you WANT to hear is far away.
The noise you DON'T want to hear is in the next room (blender, vaccuum,
fluorescent light, etc.)

> A *partial* shield can then have some effect in differentiating the
> fields from far sources as compared to near sources. But if the
> shielding is *complete* for either field, no EM signal will be
> received. That's why the shielded loop antenna must have a *break*
> in the shield.

Not a break, but a loose or poor shield. I did mention that,
I'm sure of it. I said "chicken wire cage". I'm almost positive I
did. Also, my unit has one end open with a pigtail of randomwire so
I can find my source, then zero in on it, using S/N ratio to cancel any
noise the weak pigtail might bring in with the strong signal from the
loopstick. I'm sure I mentioned that as well. I hope.....sq

All the sophisticated theoretical discussions this thread has created
in terms of magnetic vs. electrical fields and the nature and
propagation of RFI notwithstanding (interesting though it is!), I've
discovered that a vertical whip (a 2m band short rubber duckie for ham
radio no less(!)) feeding a one-transistor amp and stuck in my window
does a reasonable job of killing the computer hash. Perhaps a
magnetic-mode antenna would work better, or perhaps it would work
worse, but I think either will work fine if you put enough distance
between antenna and computer. :-)
I've built a prototype amp using a 6" 2 meter ham (!) rubberized whip
as the antenna rod and a low-noise bipolar NTE10 as the amp.
All the very sophisticated theory discussions which Steve Quest's
comment above has sparked aside, I've found that by sticking the

amp in the window in the other room, the computer hash is nearly gone. Simple :) Of course, the sucker has too much gain and overloads now, so I'm leaning toward a JFET. (Abandoned MOSFET due to static sensitivity -- this thing will be mounted outdoors ultimately after all.)

Yes, use a 12 volt gel cell or an old car battery or a good regulated
power supply. If you have to ask how to hook it up, what luck do
you think you may have trying to repair it, unless its a broken
belt on the deck or something?

Some lap link cables provide a serial path. This is an easier way
to capture a file as it remains intact and moves in a normal way.
Check your dos book on how to send a file out the serial port. You
will need the mode command to configure the port first, or just let
the lap link program figure it out. Best luck KD3SH

Jim,

You and Tom Bruhns, who emailed me about this, are correct. As Tom pointed
out, there should be only a TEM wave in the resonator, so no coupling from
one section to the other. I was thinking more of a helical resonator, which
isn't the same.

I apologize for the error. The suggested SPICE models should work. Thanks
to both of you for correcting me.

You could save the received signals in a buffer and when the timing is uncertain, re-examine the buffer and try to make a better estimate for the last few samples and use that timing for recovering received character. This will require a reasonably good signal to noise ratio (SNR), since otherwise the uncertainty about a mark/space or space/mark transition can be either due to noise or jitter in the timing (bad fist).

The problem with automatic decoding of code sent with a straight key is that it is basically asynchronous in each element and you must get a quite sharp transition, i.e. get the 3rd or even 5th harmonic of the baseband waveform and thus require 3 to 5 times the nominal bandwidth i.e. suffer a 5 to 7 dB SNR penalty compared to synchronous modulations. If a keyer is used, the dot clock can be extracted from a few character and the problem is mainly to locate the start of each character and then apply the recovered clock rate. Not so sharp transitions are required and the bandwidth could be reduced improving the SNR.

FCC Expected to Unveil Plans For Two Airwave Auctions

WASHINGTON -- Federal regulators are expected this week to set plans for two long-awaited auctions of valuable airwaves, including one for an emerging wireless technology that could bring new competition to the local-telephone and cable-television businesses.

Wireless operators, long-distance phone companies, electric utilities and telecommunications entrepreneurs are eager to bid for licenses to use huge chunks of the amateur radio spectrum to transmit voices, pictures and data.

Wireless Auction

Up for grabs: Licenses to use most of the amateur radio megahertz of electromagnetic spectrum in each of nearly 500 markets nationwide. Repeater frequencies are much in demand by those with the following: Uses: Transmitting voices, pictures and data via small, flat antennas that can rest on a windowsill. Expected bidders: All sorts of telecommunications companies -- but Baby Bells and cable operators will be barred from bidding on licenses in their home territories.

"While the auctions for PCS frequencies were very specific about how the frequencies could be used, rules governing LMDS usage are more liberal and for a bigger chunk of amateur radio bandwidth," said Michael Sprayberry, director ofwireless strategy for MCI Communications Corp.

New Radio Service

The auction rules have been delayed in recent weeks because FCC commissioners couldn't agree on what amateur radio spectrum would be available.

The technology operates with small, flat antennas that communicate with larger antennas mounted on towers. It has tended to work poorly in heavy rains and fog, but industry officials say they are working to fix the problem. Operators also could run into resistance from cities that increasingly are blocking the construction of new antenna towers. However ham towers could be seized as the FCC has decided that the amateur radio service no longer serves the public necessity.

From: WA2RCB@N3ACL.#SEPA.PA.USA.NA
To : K1OIK@K1UGM.#EMA.MA.USA.NA

Yes, DX'ers are a unique breed of people Burt. My guess is that
if their wife was next door in the kitchen gagging on a piece of
fried chicken bone, and there was a rare-dx station on the air
at *ezactly* the same moment, 98% of the DX'ers would choose to
let their XYL's writhe on the floor and turn screen-saver VCR *blue*
first before missing the opportunity to work Kuntakintae in Lower
Gibipp. Reminds me of a funny event from a few years ago, when I was
a Director in a radio club. Had a director's meeting at this guy
house. After the business was over, went into this guy's shack.
(He was a big-time DX'er here in NJ - having worked 300-something
countries) He seemed to get somewhat irritated when I did not
share his enthusiasm for DX. After the 3rd attempt to get me to
pay some kind of hommige to him while sticking a *framed* QSL in
my face from some filthy rich ham who runs a sweatshop in Puerto
Rico who spends 98% of his time running to mud-huts in Africa in his
Lear jet. I then told him I did not give a rat's --- about DX. (I only
did this because he was so damm adamant about DX as being as important
as the second comming or something...) Well, I thought he was going to
toss me out of his QTH, but he seemed to not have the gutz for that, so
I retired to his living room to drink as much soda and chips he put out
and laugh about this whole incident with 2 friends of mine who were
there and shared my humor ove this whole screwball funny incident.
(he has put out several pint-size bottles of Coca-Cola...I had my CIA
type trench coat with me, and pocketed 3 of them just for funzies...)
So Burt, there U go, DX'ers: Ham radio's greatest mutual admiration
society. Almost as bad as contesters who run illegal power...birds of
a feather...

"SOCIETE ANCIENT TELEGRAPHERS INTENTIONAL REDUCIO EXTREMIS"

-- WORKS ONLY DX AWARD --

In recognition of an extraordinary operating accomplishment, amateur
radio
operator _________ is hereby awarded the prestigeous Works Only DX
Award, based upon the fact that said operator limits his contacts to DX
STATIONS ONLY, and has not, within the past 6 months, had any on-the-air
conversation (either by CW, phone or other operating mode) with any
other
operator residing in his own country.

In addition to denying himself the pleasure of chatting with his fellow
countrymen (in dedication to his single-minded pursuit of rare DX
contacts),
said operator has achieved further distinctions. The following special
endorsements to this certificate also apply:

( ) Works only stations from countries from which he has not already
received
a QSL card.

( ) Devotes at least 6 hours each day to monitoring packet cluster
spots

( ) Exchanges only minimal information, to avoid unnecessarily
prolonging
contacts

( ) Abruptly terminates any domestic contact which may have been
erronously
made during the heated pursuit of DX

4051. Stick a fork in ham radio

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-13 00:00:00 UTC
From: Burt Fisher <burtfisher@geocities.com>
Message-ID: <3350C0FA.51A1@geocities.com>
Source record: 95018
Cross-posted to: ec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc,rec.radio.amateur.policy

It has become evident that the ex-service now hobby is done:
Stick a fork in it!

It serves no one that cellular doesn't.
We are not unique, look around. Everyone has radios, phones.

Most operators are tunnel-visioned, goat-headed people. They think that the license, the code or the younger thinkers are the problem:

I contend it has been the ARRL, NTS and the volunteer exam/incentive licensing that has did it in. To many "elite" people who must complain when someone says what they want to say or operate as they want. I once thought packet radio might go somewhere but we never got over 1200 baud.

Now if the fact that cell phones were allowed in the Olympic venues but ham radios were not doesn't show you something, listen to a voice traffic net like the Indiana Traffic/DewDrop/Mushroom Cloud Spotting net some afternoon. NTS needs to tie up a radio frequency to handle fake messages for people who are too lazy to pick up the phone or mail a letter to mom wishing her happy birthday. Give me a break! They even pass phone numbers of recipients AND NOW even E-MAIL ADDRESSES!!!A JOKE! Right?

I am just waiting till all the VHF spectrum is gone, along with most of the HF spectrum. Then we will all be CBers, like many elite hams call others in order to degrade an opinion they can't stand to debate.

Structure, as per ARRL, has not kept up with the purpose of the "service"
That service used to be needed, now we are "bookmarks"for other wireless services. The latest band gone is 2300 MHz for wireless internet, not for packet, which should have pushed been years ago, along with:

902-928 GONE well "shared" by every device that would hear hams! Lesson?
220-222 GONE
144-148 soon to be gone
222-225 soon to be gone
430-450 soon to be gone

Do you get the picture?
Maybe I drew one for you...

Hi Guys,
Sorry this is not strictly homebrew but I don't know where else
to post it.
Does anyone know the arrangement of the diode matrix board on the Tait
T500? I need to alter it's frequency coverage within the original band,
in this case circa 170 MHz
The info doesn't appear to be available in the UK and I have just spent
an hours phone time searching the Web with no joy.
Thanks... Trev ...-.-

4055. Help w/power distro block

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-13 00:00:00 UTC
From: Steve Jackson <steve@gnosis.slac.com>
Message-ID: <01bc4815$4ae55d70$ca4f9fcf@n3vzl-1>
Source record: 95022

Greetings everyone --

I'd like to build a device that will provide a clean 13.8V source to my mobile equipment. I've been told that the best way to get rid of alternator noise is to feed the power right from the battery post and to even send the ground all the way back to the battery as well.

I have an idea for a project, but don't know how to go about doing it. I want to make a distribution block that's fed from the battery. I expect it to be a block of wood about 4"x5"x0.5", and I'd like to put 8 screw terminal pairs on it. 4 of the pairs would be unswitched and the other 4 switched by the ignition. I'd mount it underneath the console for easy wiring of the gear.

I think the switching should either occur when

a) the power fed from the battery increases beyond 12V, or

b) *any* voltage is detected from an already switched fuse.

The latter would be better because the switched pairs would activate just by turning the ignition key to the ON position, and not necessarily starting the car, as the former requires.

I also don't know what size wiring would be needed to aptly supply such a block. An old acquaintance runs 4 car batteries in his pickup. He ran wiring that was comparable to those wire-rope bicycle locks. About what AWG is that kind of wiring? 14? 10? Should I use a thicker wire for the ground than the positive? Should I filter the power at all, or is the battery clean enough?

Also, how would one wire the two switching types above? Especially the latter method of using a switched fuse to activate the switched terminals. I think a relay would be useful there, but I've never wired one up.

Please forgive the simple nature, I'm a "commuter ham" who eventually learned the original meaning of a "traffic net". :-)

Thanks and 73

Steve

The Brother label makers have a clear tape w/ black type and maybe clear
w/ white at this time. You may choose fonts, size and mirroring for
adhering on the inside surface of clear panels.

Mini-Circuits has a Web page at : http://www.minicircuits.com
I believe they have the complete catalogue available online as Acrobat
(.pdf) documents.

Their phone/FAX numbers are:

(718) 934-4500 (417)335-5935 Fax: (718) 332-4661

And they can be contacted by email at : postmaster@minicircuits.com

I think you can buy small quantities and pay with a card there.

It looks as if our resident knocker is at it again, though April 1 was
two weeks ago!

However the concept of auctioning one and two letter amateur callsigns to
the highest bidder (rather than through a lottery system) has
attractions. Here in Australia we floated the idea (tongue in cheek)
that those with two letter callsigns should give them up and have their
callsign re-allocated to the highest bidder at a public auction attended
by all amateurs (on April 1, 1996). That created quite a stir, because
most amateurs want a callsign that's either very close to their initials
or very short. I suspect that a proposal to auction attractive callsigns
would raise even more controversy than one to auction some of our bands.

As this is rec.radio.shortwave I was using the FCC definition of
shortwave: 3-30 MHz. So the 486 MHz is a non sequitur. ;)

>now. :)

If they are smiling, they are smiling at you. An electro*static* field
is what you get when you rub a cat's fur. It is what a Windhurst machine
or Van de Graaf generator produces. It is the field between the positive
and negative poles of a battery. By definition it is *static* which means
it is unvarying. There is no electrostatic component to a radio wave.

There is an electric field vector which is part of an EM wave, but it
is *not* static. It is a dynamic field which varies at a rate corresponding
to the frequency of the signal. Hand in glove, inseparable from the electric
field vector, is a dynamic magnetic field vector. The energy of the EM wave
is constantly handed back and forth between the electric and the magnetic
fields as the EM wave propagates. Suppress *either one* and you suppress
the energy of the EM wave. One cannot exist without the other. This is a
fundamental fact of electromagnetics.

If you try to separate them with a Faraday shield, a counter EMF will
be induced on the surface of the shield. This will reflect the EM wave
just as a mirror reflects light (and for the same reason since light
is just extremely high frequency RF). None of the field energy, either
electric or magnetic, will pass inside the Faraday shield (assuming
the shield possesses adequate skin depth to be called a Faraday
shield at the frequency of interest).

donrm@sr.hp.com (Don Montgomery) wrote:

>Anyone have any new ideas on lettering/labeling the panels of your home-
>brew projects?

I have a couple of methods that work pretty well, the simple one
first:

Design and print-out the label using a computer and a laser or inkjet
printer.
Using a do-it-yourself laminiating sheet, cover the label with clear
plastic. The material I use is called Cleer-Adheer, C-Line #65001,
from office supply stores.
To fasten the label to a panel use 3M transfer tape (the best way), or
3M Super 77 spray adhesive available from a hardware store.

A real neat way to do it is this:
Using a laser printer, print the label on "Toner Transfer System"
paper. This paper has a resin coating that is water soluble. I
believe Press and Peel Wet is the same thing. I bought this at a
local electronic parts store.
If you want color in your image, use the product Ibifoil from Ibico.
You can get this at office supply stores.
Next put several light coats of laquer over the printed image. Be
careful because the laquer solvent can dissolve the toner and cause it
to run.
After the laquer dries, soak the image in water. It will float off
just like a decal used for model airplanes.
Apply the decal and after it is fully dry, coat the panel with a light
coat of laquer.
Note: It may be necessary to apply a little musalige sp? glue to the
panel to make the decal stick. Using the glue dissolved from paper
shipping tape works well too.

>predominately either field.

Amen. Just because the noise is from an "electrical" appliance, or
because we like to call it "electrical" noise, it does not mean the
induction field area is E-field dominant.

And certainly in the far field there is no difference at all in any
case, and even in the induction field areas the effects of direct
coupling decrease very rapidly with distance.

There is no clear-cut distance where everything suddenly changes, but
in general the receiving antenna has to be "right on top" of the noise
source to have appreciable or dominant inductive field coupling.

>On LF and MF there can be benefits for using a magnetic loop, since
>there can be quite a lot of noise sources within the near field. On HF
>and VHF the near field is so small that there simply are not room for
>a lot of noise sources :-)

Then I'd spend some time cleaning up the area the antenna was in, or
move the antenna.

You can be sure ALL of the noise sources have radiation and electric
fields, right along with the magnetic fields. It's just a wild guess
to say a loop would be better.

If I place a small loop and a small amplified whip next to each other
on my bench, they receive with exactly the same S/N ratios. The
advantage of the loop is the null is more sharply defined, and it is
easier to null a single source.

If you analyze the loop carefully, you will find there is no
advantange to "shielding" a properly constructed antenna.
The electric field response always remains, there is no way to
eliminate it. The largest effect is the shield acts like the antenna,
and simply couples the e-field energy right into the inner windings.

If the antenna is improperly designed or constructed, and the system has poor common mode rejection, then a "shield " might help.

The stuff about creating an antenna that responds only to magnetic fields is a myth.

I agree if you could build an antenna that only responded to magnetic fields, you wouln't hear any noise. But you also wouldn't hear any signals with that antenna.

Roy -

You might go to Benchmarq Microelectronics WEB page:

http://www.benchmarq.com

There are a number of other semiconductor companies that
have Lithium-Ion chargers i.e. Motorola, Sanyo, Maxim (MAX745)
http://www.maxim-ic.com, Shoreline Electronics Inc.
(408) 987-7733.

Generally the longer the time you take to charge a battery
the less demand on the charger and less destruction of the
battery occurs.

I think the best battery charger is Rich Measures design
in the September 1988 Ham Radio on page 18-21, titled "The
Weekender An Easy-To-Build NiCd Pulse Charger.

Regards,

San

I saw this on Page 126 of the ARRL's publication: Solid State Design. A two transistor oscillator for 10 MHz. It used 2N3904 transistors (weird) and the author claimed very low phase noise.

I'd like to reproduce this circuit, but I'm stumped by some missing information: There is an output transformer with 3:1 marked under it. There is no other information about it, however. No core or winding information, no model number to cross reference, or anything of the sort. Could someone give me an idea of what I should put there?

Were the ferrite beads in the article anything special? Anyone know what kind they were?

Also the book mentioned that, due to avalanche voltages on the base, the life of the transistor would be shortened. Does anyone know by how much? Is this oscillator going to self destruct in a couple of minutes? Days? a Year?

Is there any other literature about this oscillator? My 1996 handbook mentioned 1977 as the year it was published. Can anyone point me to a reference?

Prior to a demonstration, have a good talk with your Patent Attorney. A
PA who has experience in the "art" will show you how to protect yourself
(to the extent that that can be done) and can advise on the engineering.

I talk to a number of inventors in a year's time - everyone was
concerned about theft. However, some inventions can not be protected,
some are not worth protecting, and a few are magic. The Patent Office
still has the right to receive a model of an invention. When an
invention looks like it is using magic, the Patent Office will want a
demo. I have helped two inventors with inventions that could have
sounded as if they used magic - the trick is to be sure to dispell that
notion in the patent application.

Books are fine, but a PA with whom you are comfortable is invaluable.

(Yes, I do use a good spell checker with my more important notes.)
Good luck! Mac

Hi everyone:

I've been giving this some thought and I thought it would at least be worth considering. I'm BIG into QRP, but since I'm still a no-code techie, I thought I'd try doing a rather somewhat unique form of QRP.

I have a RS TRC-502 49 Mhz. transceiver that I'd like to convert into 6 meter FM simplex. Now given the band's most recent activity over the last year or two, coupled with the fact we are starting to get back up on the upside of the sunspot cycle, I thought I'd at least give it a try.

My problem is finding places that sell 6 meter conversion kits (with CTCSS tone board) and 6 meter crystals. Anyone have any ideas as to where I might go in order to get these parts???

My rationale for wanting the tone board is that here in the Denver area, 52.525 Mhz is now linked to a 440 Mhz. repeater that gets a fair amount of use, but the repeater is now PL'd.

Any ideas, useful tips and other such information would be greatly appreciated!! :-)

I look forward to your replies!! :-)

73's for now my friends!! :-)

> get by at constant-current or constant-voltage charging, or are they fussy
> and require special charging circuitry like NiMH and rechargeable

If anything, Li-ion batteries are MORE fussy than NiMH. What's worse is that they can catch fire or explode if not properly charged or discharged. Probably the best thing to do is contact the computer manufacturer...this may be a problem with their charge circuits and they may be open to replacing your laptop.

Not knowing what the rated current capacity is, it's hard to give advice. Generally don't charge at more than a 1.5C rate, keeping voltage constant also. Cells rated at 3.6v should be charged to 4.2v +0, -20mV for a full capacity charge. Again, don't pour too much current into the cell! If the cell is rated at, say, 850mA you will could safely charge it at 1.5A. If you remove the safety circuits from the pack you may be taking quite a risk with playing with these things. Please be careful.

I need some knobs for the Heathkit HR-10, HW-16 series radios.
Specificaly I need the AF-Gain, RF-Gain, etc size knobs. I need 2,
but will take what ever you have.

I also need an original manual for the HR-10 Receiver (will take an
HR-10B), and HG-10B VFO. I already have copies, so I am just looking
for originals if available.

Thanks and 73's

David

> Quantum mechanics "snow-jobs" are impressive (I guess) but do not
> contribute to this topic.

You missed the point. I could (with more justification) say 'Electromagnetic "snow-jobs" are impressive but do not contribute to this topic'.

I will spell it out. Just as one need not normally use the full power of quantum electrodynamics to accurately compute phenomena at radio frequencies (and indeed, one will be thoroughly confused), one need not use (or be confused by) the full power of Maxwell's equations to accurately compute electromagnetic phenomena on scales small compared with the wavelength.

The quasi-static approximation is widely used in engineering and physics. In this approximation, loops emit and respond to the magnetic field only. Dipoles emit and respond to the electric field only. Every time you draw an "inductor" or a "capacitor" in a schematic you are using this approximation. This approximation accurately yields the response of a *small* loop or dipole antenna to a passing electromagnetic wave, and accurately yields the interaction of a pair of small loops or a pair of small dipoles a short distance apart. In its simplest form it predicts that a small loop and a small dipole will not interact: if you take this to mean that the interaction is relatively small over a short distance you will be correct, but if you need the magnitude of the interaction you will need a more sophisticated approximation.

This approximation can, in fact, be seen as part of a formalism that provides *exact* solutions to Maxwell's equations in radiating systems. This is the theory of "multipole fields". In this formalism, the quasi-static terms are explicitly present, along with additional terms. Electric and magnetic phenomena are represented by separate terms. Multipole fields are not often used in engineering (mostly, engineers need workable approximations, not mathematically exact solutions of idealized problems), but they are extremely important to theoretical physicists (in no small part because they keep electric and magnetic phenomena properly separate).

> There is no such thing as a curl-free radio wave (noise or otherwise).

If I wanted to be this absurdly fussy, I could say that the plane wave solution you get from the source-free equations can never

occur in reality, since it has both electric and magnetic field
vectors transverse to the direction of propagation. Although this
is a perfectly valid solution to the equations, there is a theorem
that asserts that no antenna can radiate such a field. In practice, of
course, the plane wave solution is a perfectly reasonable approximation
of the field when one is far from the radiator. The radial fields
are insignificant, although theory insists that they must be present.

There are many practical situations in which the curl is insignificant,
and may be ignored. In the topic in question, the fields are not
"radio waves", but quasi-static fields very close to an EMI source.

> Loop antennas can be analyzed from the standpoint of electric fields or
> magnetic fields and there is absolutely no difference.

We agree. However, there's a huge difference between a loop (responds
to curl E) and a dipole (responds to E itself). In some situations
this can yield very different behavior.

From: stoskopf@tri.NET
Message-ID: <3351A220.3DEA153A@tri.net>
Source record: 95040

This really is a question for Sabin, but I seem to have lost his address and thought I might stir some discussion up anyway.

I'm building a new 160 RX as an alternate to the old one with a 9 MHz IF. This time I'm going to use one of the Collins Torsional Mechanical Filters at 455 KHz as a roofing filter for a DSP rear-end using the Analog Devices evaluation board. A real chance to learn something (I hope). The SSB filter is $91.60 in singles.

The specs on this filter have a good intercept point of 20 - 40 dBm. Apparently they corrected some early problem with the internal transducers on other models that resulted in a lower IP on those models.

Question: I have a couple of PN 526 9700 040 filters, BW 3.1 KHz with CF 253 KHz which I could use with tighter RF filtering. Any guesses as to intermod specs on these?

BTW: The older automobile radios used this IF and late night BC band DXing was a pleasure on long road trips. Clear channel stations were really on clear channels!

Right-angle drives for vertically mounting vacuum variable capacitors, et cetera: Multronics-Cardwell @ 516-957-7200, 80 East Montauk Highway, Lindenhurst, Long Island, N.Y. 11757.

The Cardwell rt. angle drive replaces the Jennings vac. variable 1/4-23 drive shaft collet. Be sure to set the vac. variable C to min. C before removing the collet.

No, it's still valid. Tubes running in AB without or with grid current
are
AB1 and AB2 a usual. In the semiconductor world, it's AB and nothing
else.
It was something he didn't know.
Has someone seen a transistor draw grid current? :-)

I don't have that info myself, but a call to:

Rockwell Filter Products
2990 Airway Ave
Costa Mesa CA 92626
Phone 714-641-5311

Should get the info. Yes, early problems with transducers have been
fixed since the early 1970's. Your filter may be one of the later ones,
but I do not have any catalogs.

For Sale:

Used power transformer for Kenwood TS-520/S/SE transceiver.

I bought it from a Kenwood service center in Dallas, but it turned out
that I didn't need it after all. It's in clean, in good shape, and is
ready to install in your rig.

This would also be a great transformer for a p/s for your homebrew
200 Watt class transmitter! The high B+, when voltage-doubled with
100 uF over 100 uF, is 950 VDC (no load). There are also low B+
windings that give about 300 VDC, 200 VDC, 100 VDC, and a negative
bias supply. Filament supply is 12.6 VAC. Primary is 115/230 VAC.
It was designed to power a 12BY7A and two 6146s, plus the 12 VDC
of the rest of the transceiver.

It may also work in the TS-820/S but I'm not sure about this.

Price is $60 (exactly what I paid for it) plus shipping from 762xx.
I'm told that brand new ones are $125 each (if still available).

Email me if you're interested in this nice transformer.

73,
Dean K5DH

Your biggest prob will be the naysayers in the world. Of course this
applies to anything. Let me ask: do you have access to an old sweep
generator? With schematics?

You can feed your signal into splitters, sweeps, amps, dividers,
digital circuits of all sorts and have the stuff show up on the screen
any way you wish.

And you don't need to alter thescreen at all.

use an old VIC-20, and feed into its circs and have even more
possibilities. Look it up.

I get a chuckle out of advertisements that say they have a transistor
PA that is AB1 or AB2.

I wonder how on earth you get a transistor to not draw, or draw, grid
(or base) current!!!!

Indeed all solid state amps are neither AB1 or AB2.

They are AB.

In QST there is a new class E amp. It is a MOSFET in class C, with a
third harmonic trap in the gate.

RCA did this in the 50's with broadcast transmitters, and acheived
90% efficiency. It was called a class C PA, but I forgot who the
credit went to back then.

In the 70's it was "re-invented" and called class E.

Source record: 94979

A very simple circuit which requires no connections to the TV set may be found in Popular Electronics for Sept. 1982 and is by Larry Reagan. As Reagan describes the operation of the circuit: "The TV Scope detects the flyback pulses and synchronizes its operation to them. It then generates a controlled noise pulse. This noise rides right through the TV tuner without using an r-f carrier (just like the EMI from the vacuum cleaner.)" The audio signal being observed modulates the vertical (not horizontal) trace, apparently by affecting when the noise pulse is emitted.

Anyway, the circuit works pretty well and you soon get used to the vertical trace.

Mike,

I found the device S-AU3 on Toshiba's site. If you have the Adobe
Acrobat Reader check out the datasheet at:

http://www.toshiba.com/taec/components/Datasheet/S-AU3DS.pdf

Not sure if the S-AU3 datasheet is sufficient, but below are a few of
the specs:
Freq. Range: 430-450 MHz
Output Power: 10-15W
Power Gain: 18.1-18.7dB
50 ohm impedance
DC Supply: 16V for VCC and Vcon
RF Input: 300mW

Pin-1. RF input
pin-2 V1 Vcon
pin-3 V2 Vcc
pin-4 RF output
pin-5 Ground (flange)

>worse, but I think either will work fine if you put enough distance
>between antenna and computer. :-)

My experiences parallel yours.

With antenna's just a few feet from the house, a short whip is as
quiet as the loop.

It makes little or no difference at all if I use a whip or a loop in
S/N ratio, unless there is one point source of noise I can null with
the loop.

I've NEVER measured any difference at all by adding a "shield" to any
loop.

The clearest advantage is to MOVE the antenna away from the noise
source.

>credit went to back then.

Tyler (of Marconi) wrote the paper we all use in 1948 and published it in IRE. When you read it you'll find Tyler was interested in improving the second harmonic return--where the efficiency comes from--and he did it with 3rd harmonic traps

>In the 70's it was "re-invented" and called class E.

It was used all through the 60's at Gates in the BC-5H, BC-10H, and VP-50 transmitters. When PDM came along, the MW-50, VP-100, MW-5 and MW-10 all used Tyler circuits. We called them Class D, not Class E. Technically Class D is a misnomer since it's really switching service. But it adequately described the intent of the circuit and the result.

You can find a similar circuit in the Continental Electronics Screen-Impedance Modulated Doherty amplifiers. The screen bypass of the carrier tube is parallel resonated to the third harmonic. This also improved the efficiency significantly.

Just so we leave no stone unturned, you normally see the Tyler circuit implemented using parallel-resonant thrid-harmonic resonators in the grid and anode leads. We did have one 250 KW transmitter here once that was too efficient. It's sister (on another frequency) operated quite normally. But this one transmitter's efficiency was so high we started questioning the metering. At that power level you don't check the load and input metering in a few minutes; it took a week. Turned out the metering was right. And the reason was a nice series resonance at the third harmonic from the carrier tube anode to ground. This low-impedance at the third harmonic worked just as well as a parallel resonant circuit in improving the PA efficiency.

[Lovely you say; not exactly. Unless the Carrier and Peak tube efficiencies are somewhere near the same value the crossover distortion gets out of hand. We had to kill the third-harmonic resonance to get reasonable performance data.]

And that's the news from Lake Woebegone.

Uhh, that would be a DE-15-S or DE-15-P. The DB shell is the size
most commonly used in RS-232 applications. The DE shell is the size
used in the IBM AT serial port, and the VGA connector, as you noted.
The only other commonly used 15 pin D-sub connector that I can think
of is the PC game port connector, which is a DA-15-S, I believe.

In summary, the notation Dx-##-S/P describes three things:

1. The character following the 'D' is describes the size of the shell.
2. The numeric value describes the number of pins.
3. The S or P describes whether it has sockets (female) or pins (male).

There are five industry standard shell sizes; DA through DE. The sizes
increase in dimension starting at DA, through DD, and DE is the smallest.

Sorry to get all pedantic on you, but if you've been searching catalogs
or databases for 'DB-15', you may be short changing yourself. This is
mistake a lot of people make.

Now that I've said all this, I hope I've gotten all the details
right :-) Most of it is from memory, but I'm fairly confident about
it's veracity.

Good luck in your search.

4123. Storno 6000 interface with PC

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-15 00:00:00 UTC
From: smcyber@aol.com
Message-ID: <19970415224100.SAA09305@ladder01.news.aol.com>
Source record: 94990

Hi Everyone

Has anyone interfaced an Ex PMR Storno 6000 series (2 metre) with a PC?

EF software and the EEProm spring to mind

If I'm on the wrong newsgroup, sorry please advise where I might look

Regards SmCyber.

Burp is a lonley,frustrated old man.If Amateur radio died,he would
too!It is obviously his life!!His daily routine revolves around it!
He,most likely,was severely humiliated in some way by a HAM/HAMs and
this is his way(in his sick,pathetic mind)of 'getting even'.
I have watched him make a fool of himself since the old BBS days.He
will continue to do so as long as his feeble old fingers will type.
One thing I never really understood is,if Amateur radio is so bad,why
did his daughter get her ticket?He used to brag about that,but that put
her in the same group of people he so despises!!Strange!
Ko4qC
Yes,I know I 'said' Burp.Almost the same thing as a FART!!

This isn't necessarily weird. 2N3904 transistors have a very
high DC beta. This might improve phase noise and temperature
stability.

>
>I'd like to reproduce this circuit, but I'm stumped by some missing

Probably a Mini-Circuits T9-1 would work.

>Were the ferrite beads in the article anything special? Anyone know
>what kind they were?

I don't have the reference in front of me, but in general bead
material isn't very critical if they're just parasitic
suppressors.

>Also the book mentioned that, due to avalanche voltages on the base,
>the life of the transistor would be shortened. Does anyone know by
>how much? Is this oscillator going to self destruct in a couple of
>minutes? Days? a Year?

That is a problem for multi-cell RF transistors like 2N5179's.
You can ruin those in a few minutes if you abuse them enough, but
I have read that the process can take months. The symptom is
that they have no RF gain anymore, but still work OK at DC.
That is how you can tell this process is taking place rather than
you simply burned 'em up. I don't believe the 2N3904's are made
that way, so you should be OK. (Another reason why he used
2N3904s maybe).

>Is there any other literature about this oscillator? My 1996 handbook

4126. Re: L. Gumm, K0HFD's oscillator circuit

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-15 00:00:00 UTC
From: Linley F Gumm <Linley.F.Gumm@tek.com>
Message-ID: <33542378.62C9@tek.com>
Source record: 94993

Since my comment on Richard Karlquist's and Jake Brodsky's posting is lengtly I posted it as a new Item.

Richard Karlquist's comments about the oscillator circuit are entirly correct. Here are some more details from the designer's mouth.

The oscillator circuit is the result of attempting to build the lowest phase noise device possible. Two basic principles were used: maximize loaded Q and maximize the signal to noise at the amplifier's input terminals. Since the oscillator was designed to operate at 10 MHz, the 2n3904 was fast enough. It also features a 6V base-emitter breakdown voltage, one of the highest available in a moderate speed transister. This allows boosting the amplitude at the base up to about 5 Vpp without starting a breakdown process at the base that increases the oscillator's phase noise. The 2n3904 is also reasonably quiet in the audio frequency range so its noise contributes less close-in phase noise than higher frequency devices.

The ferrit beads used should be the small ones with transister lead sized center holes. They are really necessary only when the layout has enough VHF parasitics so that the transisters want to oscillate. The 2n3904's can break into VHF oscillations during the period when they are turned on if the circuit is right. You can easily tell if it is oscillating if the ciruit is touchy and radicaly unstable when you touch any of either transister's leads with a short piece of wire held in the hand (this tends to stop any VHF oscillation that change the operating point). I have also had fairly good success with inserting 100 Ohm resisters in series with the collector leads, checking to make sure that the collector voltage when the device is on is not so low as to cause the device to saturate.

The output transformer can be made out of many ferrits. Choose a torrid that is about .5" in diameter. Wind about 5 quadrafiller turn on it (i.e. 4 wires in parallel). Connectet four of these wires in series to form the primary. The remaining winding is the secondary.

The only two places this circuit has been documented to my knowledge is in the 1995 Handbook, which has an excellent write-up which catches most of the reasoning, and the Solid State Design book you cited.

Hope this takes some of the mystery away from this circuit.

No, you are incorrect. The 'old DB-9', is neither old, nor a DB-9. It
is IBM's version of RS-232 on a 9-pin connector, and the connector is
a DE-9, not a DB-9. Yes, I agree, that it has 15 pins, and I never
stated
that it had any standard usage in RS-232.

The (now obsolete, apparently) industry standard, describes the
connector
interms of it's shell size, by letter, and by number of pins, as I
stated,
below. There is nothing to say that all DB shell are 25 pins, or that
all DE shells are 9 pons.

The point remains, the connector is NOT a DB-15, since it is not
a DB size shell.

I used to keep a photocopy handy, of a nice summary of this information
from a catalog by a major connector manufacturer (Cannon as I recall).
I wish I could locate it now.

You may have to give up on this one, Rod.

You and I both know that the letter following the D describes the shell
size, but for the most part this fact has been lost in an industry
that is overloaded with neoexperts and consultants.

4130. Intersil 7226 freq counter 4$ale

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-15 00:00:00 UTC
From: Brian Mork <mork@usa.net>
Message-ID: <3353C00C.7449@usa.net>
Source record: 94997
Cross-posted to: alt.comp.hardware.homebuilt,rec.radio.amateur.homebrew,sci.electronics.repair,misc.forsale.noncomputer

Intersil 7226-based frequency counter for sale.
Yes, it counts frequency (up to 10 MHz),
but it does more:

. intervals between two signals
. pulse counting
. ratios of two inputs
. periods of one signal

This is an un-encase 8" x 3" board, with no power supply
(requires 5 volts). Circuit is taken straight out of the
Intersil 7226 application notes, but also has an input
buffer chip.

Included is a spare 7226 (A input is fine, B input is broke),
and two spare LED digit displays.

A single 7226 itself costs $34.62 from Mouser. I'm asking
$35+shipping for the whole shebang. Usually shipping is
cheapest via UPS, but you can check on their web site.

Please let me know where you saw this post, so I can best
use the Internet bandwidth.

> antenna.

Something strange is going on here. Why would anyone put a total
"Faraday Cage" in other words a "shield room", a total short circuit
around a ferrite rod antenna?

That is not the subject that has been going on. There has been talk that
the electric and magnetic components of a radio wave can somehow be
isolated from each other by a shield of some kind. Also, that radio
waves can contain more electric field energy than magnetic field energy.

There is talk about shielded loop antennas with non-shorting Faraday
shields with open-circuits that delete electric fields and pass magnetic
fields. Or is it the other way around? I'm not sure any more.

Or that local radio noise sources are more electric than magnetic. Or is
it the other way around?

Also that the near field of an antenna is more E field than H field, or
is it vice versa?

Wierd stuff!

That's right, all the Faraday shield does is change the wave by re-radiation.

Add a "Faraday -shield " to a loop and you have a loop that acts like the "shield" is the radiator. It STILL responds to time varying electric and magnetic fields.

If, however, you rub your cat across your silk shirt and touch the cat to the antenna, the Faraday shield will reduce the STEADY dc voltage coupled to the antenna. The Faraday shield will NOT greatly change the SPARK energy coupled into the system.

Farady shield loops work best when it is raining cats and dogs, if the loop is coupled to a differential amplifier with FET's on the input.

Sorry, no you are incorrect. Read what the man
wrote, the *shell* of the plug is the same size
as a standard density 9 way. He is correct,
the shells are the same dimensions, the high
density part just has more contacts, typically
an extra row.

The McMurdo part number for a high density
15 way plug, tin & dimple, is HDE15PTD. Note
that they explicitly add an H in front. Their
number for the equivalent standard density
part is SDE9PTD. Note that the shell size
"DE" remains the same.

Note that the McMurdo part number for the
right-angle PCB socket is HDEX15SNT, this
has boardlocks ("harpoons") and screwlocks.
I don't have the number for the basic socket.
McMurdo are a UK company, but I'm certain
the equivalent part is available from a US
manufacturer.

Thanks for jogging my memory Fred.

Now I remember, it was called a Tyler circuit. The class E amplifier
in QST is a Tyler circuit.

Perhaps they should have called it class T.

I believe this is incorrect. A true Faraday shield is *transparent* to an EM wave. It is transparent to an electric field and it is transparent to a magnetic field. Its real purpose is to eliminate capacitive coupling between two conducting surfaces.

A true Faraday shield contains no "short circuits", either electric or magnetic, therefore it does impede either one.

The analogy with light does not apply at radio frequencies.

My article in May 1995 QEX, which I am sure is correct, discusses Faraday shields in more detail.

I really appreciate the replies, gentlemen.

I built an R2 receiver and was thinking of using this oscillator with it. I intend to play around with a few small value varactors to see if I can get this circuit to steer as a VCO without destroying the excellent phase noise characteristics it has.

I'm already working on a Costas Loop VCO steering circuit using the R2 I and Q channels. If I can use this oscillator (instead of the noisy signal generator I'm currently using) I have hopes for a low noise frequency standard using WWV.

I'm aware that this side project is kind of silly, because better, and probably even cheaper, reference sources exist. Still, this is ham radio, and I'm doing this for fun, not profit.

Can someone pls (nicely:) direct me to a reference in relation to the
basics of Morse code equipment. Specifically as to the design and
construction of the old style of electr mechanical sounders.
I have an understanding of general electronics, but i do not understand the
relevance of the resistance of the sounders used in the Morse system. As i
have been asked to rewind an old sounder, i need to ensure the resistance
as well as the magnetising force (gauss?)...is there a basic formula or
software tools to assist in the winding of such coils

Any help would be greatly appreciated....

Regards,
Dale

Since a 60 mV. change in base-emitter voltage causes a 10:1
change in collector current, the result of driving the base that
hard (6 volts) with a sine wave is to simply run the oscillator
in class C, with a theoretical duty cycle of a few percent.
Since the 2N3904 isn't all that fast, in practice the duty cycle
will be limited by what the 2N3904's impulse response is. I've
never seen a good analysis of phase noise in class C oscillators.
Is anyone aware of one? Linley: you should be able to take
loaded Q and phase noise as known quantities, and back out
effective input power level (or at least input S/N) by using the
usual Edson/Leeson/Kurakowa phase noise equations. Have you
looked at that? Can you tell us what the Q and phase noise is?
(I'll try to look at your original paper to see if you already
published those numbers). Incidentally, the best unloaded Q I
have gotten at 10 MHz. is about 400 using a 1/2 inch diameter
Fair-Rite #67 toroid.

None of these are actually static: they are all varying with time. Batteries change with temperature shifts, high voltage generators are difficult to stabilize, and as you rub your cat the voltage varies wildly.

Now, I agree that these may nevertheless be analyzed as essentially static phenomena. Two questions:

Why can one ignore magnetic phenomena here?

What is the criterion that distinguishes a field that may be treated as static from a field that must be treated as dynamic?

I've already given you the answers, but you don't seem to believe them. What are yours?

I'm looking for a source for narrow band +/- 5 Khz 3300 ohm IF filters.
I've searched the WEB, I located FOX and PTI however they are about $100
++ each!! Guess they don't like small quantities!! Anyone know who might
stock something like this?
Thanks

First, a comment on Rick's comments... It appears to me that the
long-tailed pair results in something more nearly class B, if you
must put a class on it. That is, the transistor whose base is
driven by the tank sees a base voltage higher than the other
transistor's base voltage half the time, and lower half the time.
If the circuit is working properly, that transistor does not
saturate.

Which brings me to a question for Linley: It appears to me that the
second transistor of the pair is allowed to saturate. Was that on
purpose? It seems to me that it would be better to not let it
saturate, but perhaps you had a reason for wanting it to.

With respect to transistors: I recently built the preamp circuit for the R2 receiver to do some bench testing on it. The circuit (attributed originally to Roy Lewallen) uses a 2N3904 grounded-base input. When I built it, we didn't have any 2N3904's in the bin, so I used 2N2222's instead. My plan was to compare it with the noise I could get from a good op amp such as the AD797, which is typically 0.9nV/rtHz and capable of extremely low distortion up to fairly high output levels. What I found was that my transistor amp would be extremely hard to beat for noise, a couple dB better than what I could do with the AD797. This didn't seem to match well with what Roy had told me about noise he had observed. I finally noticed in the transistor data sheets that the 2N2222 has a very noticably lower noise figure for low source impedances than does the 2N3904: about 1.5dB versus 3dB, for a 50 ohm source at 1kHz (essentially flat above that; 1/f corner around 300Hz for each). I have been unable to find any other transistors speced for a lower audio noise figure at 50 ohm source impedance than either of these two. (Guess the 2N2907 PNP is probably pretty good, too, and should consider it.)

Since the 2N2222A has a specified 6.0V base-emitter breakdown, and otherwise (ft, voltages, ...) is very similar to the 2N3904, it may be a very good substitute in Linley's circuit. I built Linley's circuit a couple months ago, but haven't had a chance to try it with other flavors of transistor. My model uses SMT MMBT3904's. Guess we have MMBT2222A's around too, so I could try them if I get the chance.

You guys are way out in left field on this one. I can't tell from here if it's the E or H field. In the cat example, the faraday shield *will* greatly reduce the spark energy at the output terminals of the loop, if the distances involved are small compared to a wavelength. At low frequencies, it would take a very large loop (and perhaps a very large cat) to get out of the near-field region.

What you say about EM waves is correct if you're talking about the far field. When there is an RF field of E volts per meter from a distant source, it will be accompanied by an H field of E/377 volts per meter in free space. However, this relationship does not apply when you are close to the source, or when there are objects in the vicinity that affect the fields.

At a very short distance (measured in wavelengths) from an electrically small transmitting loop, the H field is much greater than E/377. In the immediate vicinity of a small transmitting whip antenna, the H field is much smaller than E/377. For example, AO predicts an "excess" H field of about 18 dB at 100 feet from a transmitting loop at 187 kHz, and about 8 dB if you raise the frequency to 500 kHz. You get similar "excess" E-field numbers at 100 feet from a short transmitting whip at those frequencies.

Inside a cage which consists of small wires that are insulated from each other and which do not form electrically closed paths, the E field will be attenuated much more than the H field.

Getting back to the original question of what's the best active receiving antenna:

One of the responses gave a very good and concise answer. To paraphrase it, most noise sources around the house act more like "electric" dipoles than "magnetic" dipoles at low and medium frequencies. The near-field region at these frequencies also extends quite a distance from the source. A loop is usually the best choice for LF and MF; above that it doesn't make much difference.

On the 160-190 kHz LowFER band, I use an active loop about 60 feet from the house. The loop is not balanced or even well shielded. However, it gets rid of most of the crud from the household electronics except the horizontal sweep harmonics from the computer and TV set. On 160 meters a loop gives me no real signal-to-noise advantage over a wire dipole centered 60 feet above the house, with balanced ladder-line feed.

Just as a side note, back in the days before they had decent ICs to
do the job, another guy and I built an RIAA phono preamp with 2N3904s.
We discovered that breaking down the base-emitter junction, even when
the current was limited to 1 or 2 ma, would ruin their 1/f noise
performance, without much other apparent effect. Whether present-day
2N3904s would behave the same, I don't know.

>shield at the frequency of interest).

If your shield is a tube with a longitudinal slit, it cannot generate a "counter EMF" to a magnetic field parallel to its axis because it cannot support a current around this axis. It's an open circuit. Nevertheless, it is a very good approximation of a Faraday shield, surrounding its interior volume with an equipotential surface. The open ends and slit make little difference in its electrostatic properties: indeed, in most practical applications of the Faraday shield, the shield has gaps and holes.

Below the cutoff frequency of the tube's lowest waveguide mode the interior field cannot achieve a balance between magnetic and electric field energy. Nearly all of the energy is magnetic. Of course, although E is small, curl E is what you'd expect (Faraday's law is not repealed inside a shield). If the wavelength is short enough that the tube supports interior electromagnetic modes, the analysis is considerably more complicated, but that's not the issue at hand.

Such a shield will reduce the response of an antenna to electric fields (imagine testing the antenna between capacitor plates excited at the frequency of interest), and also to radial magnetic fields, but not to axial magnetic fields (imagine testing inside a solenoid). For an antenna and receiver completely inside the tube, the electric potential of the tube does not matter. Realistically, however, the tube should be grounded to circuit common to prevent common mode response to electric fields.

Such shields have long been used to improve the directionality of loop antennas by reducing their electric field response. The directionality of the electric dipole response is generally different from the directionality of the magnetic dipole response, so an antenna with a combined electromagnetic sensitivity will not show a pure dipole pattern (for a small antenna, higher order multipoles are generally negligible).

At an observatory on Kitt Peak there's an HF antenna I designed
that's shielded by a gapped Faraday shield (a gapped torus, not a
gapped tube, but the same principle). The objective is not pattern
purity but lightning protection (the *ultimate* common mode rejection
problem :-). The shield certainly does not eliminate "all field
energy": the antenna works fine.

Wrong. A Faraday shield is transparent to an RF electric field and also
to an RF magnetic field. A Faraday shield doesn't attenuate anything in
an EM wave.

The Cushcraft antenna, IMHO, is far better made than either Mosley or
Hi-Gain tribanders.
A year or so ago I replaced my old TH3Jnr with a Cushcraft A3S and I find
it seems to perform better, looks better (less element sag) and does not
blow traps when I hit it with more that 300 watts on 21MHz!! (The TH3Jnr
burnt out driven element traps each time I tried to use my 400w linear amp
on 21MHz ...in spite of the 600w pep rating of the thing!).....Buy the
A3S now!

Good luck,

Peter, G3PHO

I may be guilty of some impression of language. What we are discussing is not a Faraday shield but rather a Faraday cage enclosing a ferrite rod antenna. And the EM field inside of the cage will be zero. For a mere Faraday shield, things become a bit more complex when the shield is small with respect to a wavelength, but that doesn't matter for the Faraday cage.

The shield structure must be a good conductor, and as a good conductor it is *not* transparent to the EM wave. Just as a dish reflects an EM wave, the conductive Faraday cage will reflect the EM wave as well. The only difference is that the reflection from the Faraday cage won't be focused the way it would be by the dish. Instead, the reflection will tend to be dispersed. For wavelengths shorter than the linear dimension of a Faraday *shield*, the EM wave will also be reflected. For a shield small with respect to a wavelength, the shielding will not be complete.

But as noted above, this only applies to a Faraday *shield*, and not
to a Faraday *cage*.

To say that there is analogy between light and radio waves is error.
They aren't mere analogs. *They are the same*, save only a difference
in frequency. That difference requires a finer structure for reflecting
light than is required for reflecting radio waves, but the mechanism
of reflection is the same. Chicken wire is too coarse to reflect the
EM frequencies of visible light, but it is more than sufficient to
reflect radio waves with a frequency below 2 GHz.

>
The amplifier runs as a 50% duty cycle limiting amplifier, producing a square wave output. If one assigns classical class designation to it, it would be a class-B. The reason for trying to raise the amplitude at the base is to limit the percentage of time that the amplifier is active (and making more noise) vs. the time it is in hard limit (and making a minimum of noise).

Linley: you should be able to take
> loaded Q and phase noise as known quantities, and back out

> looked at that?
I haven't tried to apply the Leeson model to this oscillator any further than to observe that a greater Q reduces the phase noise. Leeson's model makes assumptions that do not fit this oscillator well. Understand, I designed this oscillator in the early '70s and haven't thought much about it since.

> Can you tell us what the Q and phase noise is?

> Fair-Rite #67 toroid.
>
The phase noise numbers are published and I do not remember them well enough to quote. Memory also does not serve very well as to what Q was obtained in the published circuit. Some notes indicate that I was using a Micrometals T68-6 wound with about 17 turns of something like #18 or larger. The capacitor was one obtained from and old ARC-5 transimtter. Your core with a Q of 400 sounds like about the same value I achieved.

Silver oxide is conductive; there is no need to remove it.

4178. GE MASTR II frequency changes?

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-16 00:00:00 UTC
From: Samuel Johnson <samjohnson@Bledsoe.net>
Message-ID: <3355535D.796E@Bledsoe.net>
Source record: 94945

I am setting up MASTR II's for repeater use. The only problem I have, is that the manual says to read the frequency with a frequency counter at a certain point in the radio. My point is, it has to be 9 times the frequency. In the 440 range, this puts the frequency far above the frequency counters that I have access to. Am I looking at the problem wrong? Can anyone help me decide on how to solve this situation? I have the test set, and MASTR II manuals to work with, plus the mods.
Any help appreciated,
Sam Johnson KF4GQS

I just salvaged some electronic parts from an old Compugraphic typesetter. The following parts are for sale:

12 - 25 ohm , 50 watt 3% chassis mount resistors
3 - 1 ohm, 25 watt 3% chassis mount resistors
2 - 38,000 MFD 40 VDC caps
1 - 110,000 MFD 15 VDC cap
1 - 8,200 MFD 25 VDC cap
1 - 17,000 MFD 35 VDC 45 Surge cap
1 - 6 uf 660V cap
4 - 1N1184A diodes
3 - 2N5301
Approx 275 ICs will sell as set. Contains 7521, 7535, 7539, 7531, 7541, 7450, 7423 and others.
Heavy Power Transformer. Don't know specs, but suspect it has 5 VDC and others. This item weight quite
a bit, maybe 10-20 lbs.

Make offer to me for all or part at mckellips@earthlink.net

Thanks,
Jim McKellips

I don't think so. At the third harmonic the output network presents a non-resonant load to the anode It just looks like a switching amp to me; no resonators. And the second harmonic isn't well terminated, the impedance is quite high
.
Just for fun, I modeled the 300 W output network. A good enough approximation is a 10:50 Ohm, -71 degree, Pi. Looks like the series resonant circuit comes out at 4.56 MHz. I haven't done a spice run on the drain waveform but I'll look at it later; looks to me like there's a lot easier way to do this. Maybe I'm missed something when I reverse engineered it.

I see what you are saying.

They claim in the text that C3/L2 squares the waveform. It looks like the combination of C2 and the reactance of L2 would form a high impedance tuned resonance at the anode for the third harmonic.

The explaination in the text is incorrect if you are correct.

In any event, if it does work as claimed it is like the old tube RCA transmitter I was thinking of using the Tyler circuit (except RCA used an additional third harmonic resonator in grid).

While it will reduce low frequency energy, it will not always reduce
the "spark energy" at the operating frequency of the antenna.

Let's consider a two turn loop inside a single shield broken at one
point. The actual result of adding the "Faraday shield" is the loop
behaves like the single broken outer turn is the actual antenna.

Even in the near field, the system responds very well to direct
electric field coupling.

If the original internal two turn antenna is poorly balanced, or
couples to something like a ground independent high Z input
differential amplifier, the outer shield may help. If the two turn
loop is properly coupled to a system that doesot respond to common
mode signals the main result is the outer shield holds the antenna up
in the air better.

>At a very short distance (measured in wavelengths) from an electrically

>E-field numbers at 100 feet from a short transmitting whip at those
>frequencies.

That's correct, the antenna DOES NOT respond well to electric
near-fields at all WITHOUT a shield. That is my point.

>Inside a cage which consists of small wires that are insulated from each
>other and which do not form electrically closed paths, the E field will
>be attenuated much more than the H field.

Not if it is time-varying. The result is exactly as if the "shield"
became the antenna.

The shield does NOT stop the time varying electric field. If it did,
it would also stop the time varying magnetic field. The antenna would
be dead for any signal.

>Getting back to the original question of what's the best active
>receiving antenna:
>
>One of the responses gave a very good and concise answer. To paraphrase
>it, most noise sources around the house act more like "electric" dipoles
>than "magnetic" dipoles at low and medium frequencies.

I'll assume you mean an electric field dominant radiator, vs a
magnetic field dominant radiator in the induction field coupled area.

Where is that documented????

I keep hearing people "paraphrase" that, but give me a logical
explaination of why that is "true".

>On the 160-190 kHz LowFER band, I use an active loop about 60 feet from
>the house. The loop is not balanced or even well shielded. However, it
>gets rid of most of the crud from the household electronics except the
>horizontal sweep harmonics from the computer and TV set.

My point exactly. Once you have an electrically and physically small
loop, you have the effect of low E field response in the near field.
If you installed a properly treated monopole or dipole at the same
location, I'd bet the results would be the same.

Here at my location, it makes little odifference if I use phased loops
for receiving, or phased monopoles. The only advantage of the loop is
it is easier to isolate it from unwanted feedline conducted signals.

Throwing a "shield" around the loop will only make the system better
(on the desired receiving frequency) IF the original system is
improperly coupled.

Thinking the "shield" stops response to time varying electric fields
is non-sense, as is assuming electric appliances mostly involve
electric field coupling.

> shields with open-circuits that delete electric fields and pass magnetic
> fields. Or is it the other way around? I'm not sure any more.

The slotted tube Faraday shield blocks axial and radial electric fields, and also radial magnetic fields. Only the axial component of the magnetic field (along with a little electric field regenerated by induction) survives inside.

The gapped Faraday shield technique has been around for a *long* time. Its most common application is in transformers, where it is used to insure that primary to secondary coupling is purely magnetic. This prevents electric fields from propagating undesired common mode energy.

There is no reason that this should not work for radio waves, and it has also been used here for a long time. Its application is restricted to small antennas, since induction will fully regenerate the E field energy from B alone over a moderate fraction of a wavelength.

The other way around is harder: blocking magnetic fields without blocking electric fields violates no law of physics, but there exists no material with the properties required to do a good job.

> Also, that radio
> waves can contain more electric field energy than magnetic field energy.

The problem is that while it is indeed true that traveling waves far from sources or conductors contain nearly equal amounts of electric and magnetic energy, this is only a special case. In the presence of nearby field sources or reflections, all kinds of unbalances can occur. In the real world, one does not only encounter the simple case!

Standing waves in a resonant cavity have equal amounts of energy in electric and magnetic fields, but the energy densities are uneven (anyone with a microwave oven has probably noticed this), and the peaks in the magnetic energy density don't generally occur at the same places as the peaks in the electric energy density. Thus, a

small loop inside a resonant cavity will generally see a different pattern of energy density than a small dipole. In practice, cavity resonators are often coupled to coaxial lines by loops or "probes" (small unbalanced dipoles). The two sorts of coupling structure are not equivalent. Reference books have diagrams of both electric and magnetic field lines in cavities to help engineers decide where to place the chosen coupling structure and size it to achieve the desired degree of coupling.

The extreme case occurs in the common reactive components: inductors and capacitors. Inside a capacitor, the field is almost entirely electric. Inside an inductor, the field is almost entirely magnetic.

> Or that local radio noise sources are more electric than magnetic. Or is
> it the other way around?

It can be either. Physics offers no preference. Ancient lore claims that static zone EMI is predominantly electric. However, the local EMI in my laboratory is predominantly magnetic at long and mediumwave frequencies. This is important to me because I design extremely sensitive radiation detection systems: EMI is a big problem. I suspect that my lab experience is relevant to residential problems, because the major EMI sources are computers and fluorescent lights. I haven't done a careful survey of my home, however.

I am thus sceptical of the loop antenna's claim of superior noise due to low electric field sensitivity. This is not because this claim does violence to physics (it's perfectly possible), but simply because it contradicts my experience. I suspect the real difference that some claim to have observed is due to comparing poorly balanced electric antennas to well balanced magnetic antennas. In the presence of common mode noise on the feedline, balance is what's going to matter. There have been very favorable reports on Datong's balanced dipole active antenna, but it's very expensive.

> Also that the near field of an antenna is more E field than H field, or
> is it vice versa?

Again, it can be either. Dipoles are electric antennas, with a predominantly electric static zone field. Loops are magnetic antennas, with a predominantly magnetic static zone field.

Incidentally, the term "near field" has been used in this discussion in a way that's inconsistent with its usage among electromagnetic specialists. Specialists use "near field" and "far field" to describe a phenomenon in the radiation zone of beam antennas: near the antenna the radiation intensity falls off very slowly with increasing distance. That's the "near field". The "far field" is where the intensity falls off like 1/r^2. The near field of a large microwave dish can extend for kilometers!

For small antennas, we distinguish:

1. The "static" zone, in which the fields resemble the electrostatic field that the the antenna's charge distribution would produce and the magnetostatic field the antenna's tangential current distribution would produce if frozen in time. How far out this extends depends on how accurately you want the fields to resemble the static fields: by a distance of lambda/(2 Pi) the the resemblance is poor.

2. The "induction" zone, in which electric and magnetic fields are tangled up in odd ways that resemble neither static fields nor traveling waves. The energy densities in E and B tend to be balanced better than in the static zone. This zone extends out to a few wavelengths.

3. The "radiation" zone, in which the energies are nearly balanced and the fields are nearly transverse, as required for traveling electromagnetic waves.

Is a convertion from a microwave oven to a transmitter for Ham
applications feasible? Can it be "Re-tuned"?

It seems to me that if the frequency were tuned down a bit (I think
the freq for wiggling water is ~2.1 GHz) and modulated somehow, a
Tappan would make a dandy +100w transmitter.

Phil...

Not correct. The Faraday shield prevents *capacitive coupling* between two circuits. It does not prevent Faraday coupling.

By Faraday coupling I mean that an AC magnetic field creates an AC electric field that is transferred onto an adjacent conductor by virtue of a boundary relation concerning tangential electric fields. A magnetic field, by itself, induces nothing. The associated E field is the thing that is coupled.

As I have posted before, all conventional transformers operate on this principle.

The impedance at the drain goes high at about 12 MHz; it's non-resonant and capacitive at the second and third harmonic

>In any event, if it does work as claimed it is like the old tube RCA
>transmitter I was thinking of using the Tyler circuit (except RCA used
>an additional third harmonic resonator in grid).

Naw, Tom, you can't call this a Tyler. Tyler found a way to approximate switching operation by tailoring the input and output waveforms. Looking at the input circuit, I can't see any waveform shaping that even remotely approximates they way a Tyler circuit works. You can use a third harmonic resonator either in the grid or the cathode (and anode) to get a Tyler circuit working; this doesn't have either.

Tell me which designer program you have and I'll post an analysis in that format. I'm also gonna look at the drain waveform today.

If you know anyone who rep's BE transmitters, ask them for a copy of their advertising brochure on their AM transmitters. That's a pretty good application of Class E (single ended switching). You may also wanna check out most of the solid-state offerings made by any broadcast company. Everyone tries to switch at the zero current point.

Without being too biased at this point, I'm still unimpressed. It remind me of a Thomson patent of 15-20 years ago. They took the output of an audio amplifier, ran it through an inverting op amp and presented the op amps input and output signals as the amplifier output and claimed that this was a new way for getting maximum power output from an amplifier. Say what? That had only been done for about twenty years when they patented it. Some guys are probably trying to patent toast as a bread improvement.

Then it ceratinly is not a class E amplifier, or a Tyler circuit.

It is a simple class C amplifier.

I do this all long-hand, I can't model it.

I calculate a fraction of an ohm resistive and about 30 ohms Xc at the drain at 21 MHz. I estimated the size of the inductors by the pictures and text.

You appear to be correct, this PA is NOT class E or a Tyler circuit. It is a conventional class C PA.

>Tell me which designer program you have and I'll post an analysis in
>that format. I'm also gonna look at the drain waveform today.

I use a Texas Instruments TI-58C from 1972.

When I first looked at the alleged "class E" circuit, it looked like
a third harmonic trap in the gate. The text stated the tank squared
the waveform, which I assumed to mean it presented a high impedance at
the third harmonic.

Apparently it is just a conventional class C stage.

And if the loop is properly constructed, it does NOT respond to common
mode energy. '

As I said before, if the loop is properly constructed and fed, the
"Faraday" shield does nothing.

Even in most cases of homebrew antennas, there is no difference
between a "shielded" and "unsheilded" loop.

The "shield" only helps if direct capacitive common mode coupling
exists to the feed system (via the loop), something that even the
casual loop builder can easily avoid.

>There is no reason that this should not work for radio waves, and
>it has also been used here for a long time. Its application is
>restricted to small antennas, since induction will fully regenerate
>the E field energy from B alone over a moderate fraction of a
>wavelength.

All that happens is the shield becomes the element responding to
common mode electric fields. The current induced in the Faraday shield
creates a magnetic field, and an electric field also exists INSIDE
the Faraday shield.

It couples right through to the inner loop.

The total effect is that the shield becomes the receiving element.
It's like you changed the diameter of the element slightly. The only
thing the Faraday shield really does is modify common mode capacitive
coupling, something that general;ly isn't a problem anyway in a low
impedance loop antenna.

Claims adding a shield over a loop prevents noise response are mostly
rooted in folklore.

Wrong again. Every inductor with an AC current has an associated
electric field associated with it. Lenz's law is working at all times.
The counter emf in an inductor is due to an electric field that is
generated by a changing magnetic field.

Inside a capacitor there is a displacement current. One can easily
calclate an H field that is created by this displacement current.
Textbooks contain exercises that ask us to calculate this H field.

I believe Farady, Lenz and Maxwell and Ampere decided all of that a long
time ago. But now we see that all of that is being pitched out and
reinvented.

Baloney.

A main design objective of a Faraday shield is to minimize these eddy current losses. But there will always be a small unavoidable loss. As Doty has pointed out, a longitudinal slit in the loop shield, as well as the usual transverse break, may be helpful (worth a try).

I just worked backwards and then checked my coil numbers with a calculational tool. The networks program we use (ELSIE) gave me .81, .19 and .12 uh for the inductors. The program calculated 37@-89 at 21 MHz and 9.3@0 for the fundamental.

Jim Tonne got interested and ran a spice analysis using the network shown and a regular old Pi net work. We get exactly the same voltage/current relationship at the drain of the FET whether we use sine wave drive or square wave drive. In all cases the voltage is min when the current is max & vice versa. Sine wave drive causes a tinsy bit of crossover at the trailing edge.

More as time permits cuz right now we don't see anything novel about this circuit; looks like Class C, like you said.

Can you get a copy of Pspice somewhere; it's free. I'll send you the files on the analysis.

I think you missed my point. Is your randomwire antenna, or
have you ever used a randomwire antenna that was longer than 16 feet?
If this is true, then your antenna was cut for longwire lengths WITHIN
the HF band (close to 30 Mhz).

sq

(I was only using the 486 Mhz as a wild example that even a foot of wire
is a longwire for _some_ frequency. 16' 2 1/2" of wire is a longwire
for 30 Mhz, maybe this is a better example? :)

There isn't an electrostatic component in an EM wave, however,
there is always an electrostatic field around a radiating element, and
an ionizing field if the power is high enough. Radiating elements
present both dynamic as well as static energies. You have an
electrostatic field about your body right now! To say there is _no_
electrostatic component in anything would be in error.

I haven't seen your actual article, so I didn't know until now
it was a push pull design. When a differential pair is in "hard
limit", it means that one transistor is cut off and the other
operates as an emitter follower. It is true that during the
~50% of time that a transistor is cut off, there is no noise,
but during the ~50% of time it's an emitter follower, you have
its full collector shot noise. If there is a resistor or active
current source driving the emitter, you can add that noise it as
well. This is why ECL has high phase noise. In severe class C,
you would have the transistor cut off a high percentage of
the time, reducing the time spent making noise.

>The phase noise numbers are published and I do not remember them well

>Your core with a Q of 400 sounds like about the same value I achieved.
>
>Linley Gumm

If I did the math right:

A Q of 400 at 10 MHz. is a half-bandwidth of 12.5 kHz. If you
have 0 dBm of input drive, and a 3 dB. NF in the oscillator
transistor, you should have phase noise about in this ballpark:

10 kHz. offset: -170 dBc/Hz
1 kHz. offset -150 dBc/Hz
100 Hz. offset -130 dBc/Hz

(neglecting 1/F effects).

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
April 20th, 1997
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >1000 cars!

Buyers admission is $4 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $10.00-each at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Seperate lines will form prior to gate opening
for prepaid and nonprepaid vendors

A discount sellers SEASON PASS is available for
$50 per space if purchased by April 20th.

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 146.52 and W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)

Try looking ate the ECS filters that Digi-Key sells. They have a
7.5KHz version that may work for you. I have had good sucess with
these filters. I found that by playing around with the I/O impedance
I could get the passband ripple as low as 1/4 dB.

> Dave Wilkey, N9JIT
> dwilkey@ix.netcom.com

You won't learn much about SMT by building a kit. Assembling SMT
stuff can be easily done with a small soldering iron.

The real learning comes with trying to take SMT stuff apart.
Even a simple resistor removal requires two tiny soldering irons
or a heat gun. It's extremely difficult to remove a large gull-wing
or J-leaded part without at least one heat gun...two works better, one
for each side of the board.

You can make desoldering tools as follows:
Get a heat gun with adjustable temperature. You need a "snoot" for
each size part you want to remove. Take a piece of metal tubing
that fits over the end of the heat gun. Cut 4 slots in the other end
and bend the metal into four flat sections that are about 1/8" larger
than the part to be desoldered. Make a flat metal baffle plate that's
about 1/8" smaller than the part. Install the baffle in the square
hole you made in the tubing by welding or metal tabs thru holes.
This results in a slot around the perimiter so the heat goes to the
leads
and not the part.
You need a "snoot" for each size part you work with.
You also need a vacuum pick-up tool or tweezers that will open wide
enough to grab the part.

You have to experiment with the heat setting, distance to the part
and the heating time so you desolder the part without burning up the
part or the board.

A good way to practice is to buy a SMT VGA card. You can get them
for a buck at swap meets. Practice removing and replacing parts
and see if it still works.

Good luck,
miker

A second heat gun on the back side of the board helps consiserably.

4214. Professional Faceplates

Newsgroup: rec.radio.amateur.homebrew

Message-ID: <3356D03E.69C@wchat.on.ca>
Source record: 94881

So many people have emailed me that I decided to give the
info this way.

For the faceplate of homebrew equip.
design your own using CAD and then plot it out
on " Fascal 700 " this is clear acrylic sheeting, sticky
on one side, with a peel off backing.
We get it from Unisource Canada (so they are probably
in other countries too).
It is .001" thick and designated T1S
We use Staedtler pens with our Hewlett-Packard GLII plotter.
Their part number for the HP is 31HP07K-3
That's a .7mm pen - felt tip - permanent.
They are also available in .3mm - all kinds of colours.
After the plot... let it sit for at least an hour.
Then.... wet the chassis (faceplate) with Windex (very wet)
as you peel off the Fascal ....wet the back (keep the front
dry or the ink will run!!)
That gives you an extra chance to position the Fascal.
If you don't wet the stuff .... and you try to re-position
the Fascal .... it will peel the paint right off!
We only plot the Titles and Control Legends (with neat
borders for groups of controls)
AND ... put little X's where you are going to drill holes.
This is so your rig ends up aligned.
We also plot the hole diameters ... because the guy doing
the driiling might not know what the hole is for!
Hope this all helps.
73'3
Bob

Dave,

As stated elsewhere, the real art is in removing and replacing parts.

But if you would simply like to put down a few surface-mount devices
for the fun of it and end up with something useful, let me suggest the
S&S Engineering "Digital VFO". It's a useful synthesized VFO circuit
with output to about 17 MHz (if memory serves), incorporating an
on-board low pass filter for antialiasing and an LCD display. It is
about 70% surface mount as I recall. S&S Engineering is on the web:

http://www.xmetric.com/sseng/

I decided to build one to use as the local oscillator for a KK7B
"miniR2" direct-conversion receiver. It worked as advertised after
being constructed using my patented "shaky-hands" parts placement
technique. I came away from the experience feeling that, in some
ways, it's quicker and faster to build SMT-based kits than
through-hole designs -- no leads to cut when the soldering is done.

Heaven help you, though, if you put a multi-lead SMT device down with
the wrong orientation! Unless you have the right demounting tools,
your rework technique may begin with ordering a new kit. :-)

Made a nice VFO for the R2, too!

I have no connection with S&S Engineering other than the one I made
through my VISA card.

Regards,

Mark

> John Doty wrote:
> > and capacitors. Inside a capacitor, the field is almost entirely
> > electric. Inside an inductor, the field is almost entirely magnetic.
> Wrong again. Every inductor with an AC current has an associated
> electric field associated with it. Lenz's law is working at all times.

Nope, right again. Let us calculate:

From the Pico catalog, take an inductor, #69410, 25 uH, self resonant frequency 4 MHz. We may estimate total electric field energy storage within the component from its effective capacitance, which from the self resonant frequency is about 63 pF (a reasonable value for an inductor of this type).

Now, apply 1V RMS at 100 kHz. We may immediately calculate the total mean electric field energy within the component from the capacitive energy storage relation (.5 C V^2), or 32 picojoules.

The magnetic energy storage is a little trickier (since we applied a voltage). The reactance (2 Pi F L) is about 16 ohms, so the RMS current is about 64 mA. The average magnetic field energy (.5 L I^2) is thus 51 nanojoules.

Thus, this device has, on the average, more than 1000 times as much energy stored in magnetic fields than it has in electric fields. The electric field energy is only comparable to the magnetic field energy very briefly while the current changes sign. The electric field energy thus has no significant influence on the dynamics of this device: it may reasonably be considered an almost purely magnetic device at this frequency.

At 10 MHz the situation is very different, but no sensible engineer would call this thing an "inductor" at 10 MHz.

> The counter emf in an inductor is due to an electric field that is
> generated by a changing magnetic field.

No. The the key thing to remember about an inductor is that the E field along the wire is *zero* (ignoring resistance). This is the electric boundary condition for a conductor. Along the wire, there is a *potential gradient* that *cancels* the E field due to dB/dt. A potential gradient is not the same thing as an E field. In a practical inductor, this potential gradient leads to small electric fields perpendicular to the wire, but these are properly considered

parasitics to be minimized by the design of the winding.

The EMF may be calculated by integrating the potential gradient
along the wire (if you integrate the E field along the wire you
get *zero*). Of course, it's much easier just to use Faraday's Law
in its original (integral) form (and even easier to read the
inductance out of a catalog :-). You may also cheat and integrate
the E field that would be there if the wire wasn't present, but
that's doing violence to the physics of an inductor (although in
a betatron...).

> Inside a capacitor there is a displacement current. One can easily
> calclate an H field that is created by this displacement current.
> Textbooks contain exercises that ask us to calculate this H field.

But that H field has no appreciable influence on the dynamics of
most practical capacitor below VHF frequencies (OK, aluminum
electrolytics, yuk). The effect was so small in 19th century
circuitry that Maxwell had to predict its existence theoretically
before anyone could devise experiments to detect it. A capacitor,
operated within its intended frequency range, is a pure E field
device for nearly all practical purposes. You may estimate the
energy ratio in E and H fields by analogy with the inductive case
if you wish.

> I believe Farady, Lenz and Maxwell and Ampere decided all of that a long
> time ago. But now we see that all of that is being pitched out and
> reinvented.

It isn't me that's pitching it out, it's you! Have you built a
transformer with a dipole for a secondary yet?

There was an article in 73 a few years ago concerning doing what you are asking about.

The transmitter would have the same output that tha Micro-wave oven had: 300 - 700 Watts. This is sufficient power not only to be heard a fair distance away but also enough to cause small birds to come falling out of the sky (medium rare) 1/4 Mile from your antenna.

If you really want to do this, please use EXTREME CAUTION.

Paul - K9ERG

>Tappan would make a dandy +100w transmitter.

The frequency isn't from any physical characteristics of water. Old microwave ovens ran at 915 MHz, and new ones run at 2.45 Ghz +/- 50 MHz. These are used because that's where the Industrial/Scientific/Medical allocations were made by the ITU Treaties. 915 MHz is right in the middle of a ham band and 2450 is (or was) on the edge of one. (Didn't they take part of that band (13 cm) away for other uses in the last year or two?)

If you could find a 25 or so year old Raytheon RadarRange you could have all sorts of fun jamming all the wireless LANS in town. (As I remember, they were huge suckers, about half the size of a refrigerator with a vertical sliding door.)

Yes, I think I'll build one and measure waveforms. I'll bet it is a
simple class C, from the component values.

Do you know why they called it class E, or what the textbook
definition of class E is???

The topic at hand is noise or QRN.

Please tell me what type of noise this static field produces.

A stable unchanging field must cause a VERY VERY low pitched sound.

;-)

Source record: 94802

I hear very poor audio when receiving CW with narrow (300 Hz) filter on
my TR-7.
I know that some ringing is unavoidable, but so much distortion is a
pain to ears and does not happen with my other rig (TS-950S with 500 and
250 Hz filters).
This annoyance is still here after carefull realignment procedure from
the service manual.
Maybe the audio amp has too much gain (external filtering is of some
help).
No special advice obtained on this subject from Drake Co.
Any suggestion welcome.

If I'm in the wrong group, please e-mail.
Thanks.

>Do you know why they called it class E, or what the textbook
>definition of class E is???

I pulled the original patent application and, basically, its Class E cuz it doesn't have a complementary transistor to switch with. This is certainly simpler than an H bridge but this is a tuned amplifier whereas an H bridge is much simpler to couple.

>I have P spice, but I can't figure out how to use it.

If you hadda been listening instead of picking your nose in school you'd have been able to figure out that, for the component values given in the article, the efficiency of the amplifier, as described, would be 57%!! If you wanna do a quick fix, change C2 to 470 pf, C3 to 450 pf, and L2 to 1.8 uH. 440 Watts out @ 90%. It'd take a bit more time than I have to get the output at exactly 300 Watts with 100 Volts applied. All you gotta do to L2 is change to 11 turns instead of 9 turns; total coil length of about 3".

You're using the "official" definition of "near field". The other guys are using it more colloquially to mean something like "everything inside the induction zone". This usage is not uncommon (I've even seen it in textbooks), but it can be confusing.

The near/far field distinction is mainly useful for large antennas. The "zone" distinctions are mainly useful for small antennas, especially things that aren't intended to be antennas but emit EM fields anyway.

> Not correct. The Faraday shield prevents *capacitive coupling* between
> two circuits. It does not prevent Faraday coupling.

If it makes you happier, you may substitute the word "inductive" when I use "magnetic", and "capacitive" when I use "electric". However, if *I* did that routinely my colleagues would not understand me. The normal terminology is "electric" and "magnetic".

When physicists talk about "electric" effects and "magnetic" effects, we do not mean that the field isn't fully electromagnetic. Nevertheless, there is a real distinction between "electric" radiation and "magnetic" radiation. The recognition of this goes back to Hertz, who calculated radiation using combinations of electric and magnetic fields now known as "Hertz vectors". Hertz vectors come in two varieties: "electric" and "magnetic". An electric Hertz field describes the field of a small dipole antenna, while a magnetic Hertz field describes the field of a small loop. Each describes an electromagnetic field with both E and B, but THEY ARE NOT THE SAME THING.

For antennas separated by large distances, Hertz's results show that the distinction between magnetic radiation and electric radiation is simply polarization. I believe this is the result that you attempt to reason from. Nearby, however, the situation is more complex, since the static zone field of a magnetic radiator is predominantly B, while the static zone field of an electric radiator is predominantly E.

In the future if you choose to dispute this, I invite you to compute the energy in the E and B fields in question. Failure to do this will lead you to mistake minor parasitics for major effects. For example, at a radial distance of 0.02 wavelengths from a small loop emitting a field, the ratio of magnetic to electric field energy density is about 60 (although the formulas aren't terribly complex, it was easier to look up the tabulated field coefficients in Reference Data for Radio Engineers, square them, and divide).

The coupling works both ways. Since a small loop antenna generates only a magnetic field in its vicinity (the electric field energy is negligible), it must respond only to the magnetic field in its vicinity. One may therefore compute the differential terminal voltage of a small receiving loop directly from Faraday's law, ignoring electric fields, and if you check the literature on loop

antennas this is precisely how it is done in practice. This works regardless of whether the field is a quasi-static field from a nearby source or a fully electromagnetic field from a distance: the loop responds only to the magnitude of the magnetic field.

Similarly, a small dipole couples only to the electric field in its vicinity. Consider two small antennas, one a dipole and one a loop, matched to be equally efficient at receiving electromagnetic radiation from distant sources, and oriented to have the same polarization. If you place them 0.02 wavelength from a small loop emitting an EMI field, the dipole will see 18 dB less EMI than the loop, according to the above result. In a practical situation, this might well be worth exploiting.

Again, if you doubt this, I invite you to design a working transformer with a dipole in place of one of its windings. This *must* work if your argument is correct. Please address this issue.

> And since energy must be conserved, the electric and magnetic field
> components *must* be of equal strength (though at different times as the
> energy oscillates back and forth between the electric and magnetic field
> vectors).

No. The energy does not oscillate back and forth between the E and B field in a traveling wave. The two are in fact *in phase*, so the energy density in one peaks at the same time as the energy density in the other, at any given point. I made your claim in class (as a high schooler taking a college level course in the summer) a few decades ago. Prof looked at me with pity and told me to read the book more carefully.

In standing waves you can have the oscillation you want, but not in traveling waves.

It *is* true that in a traveling wave the electric and magnetic field energies are equal (or to be fussy, the energies approach equality as the distance from the source approaches infinity).

> A *partial* shield can then have some effect in differentiating the
> fields from far sources as compared to near sources. But if the
> shielding is *complete* for either field, no EM signal will be
> received. That's why the shielded loop antenna must have a *break*
> in the shield.

An aluminum tube with a thin break is for all practical purposes as good an LF/MF/HF electric field shield as an unbroken tube, yet the unbroken tube is also an effective shield against magnetic fields while the broken one is not. You can verify this by comparing the effect of such a shield on a dipole antenna and a loop antenna (both well balanced to insure you're actually sensing the field at the antenna).

> Actually, what a loop (shielded or not) and whip do (when properly
> combined) is change the antenna pattern from bidirectional to cardioid,
> IE sharply unidirectional.

The half power beamwidth of a cardioid is something like a third
of a circle: I use cardioid pattern antennas pointed straight up
to receive spacecraft signals from horizon to horizon. A cardioid
is not "sharply" unidirectional.

> Note that the whip and loop must be physically small with respect
> to a wavelength for this to work. If they grow to be an appreciable
> fraction of a wavelength, then polarity raises its ugly head as an
> issue which must also be considered. Polarity can be exploited for
> other things, such as diversity reception, but it will have the effect
> of degrading the cardioid pattern of a loop and whip combination.

You're talking about phasing. This is used by some advanced MW
DXers, with pretty amazing results. These folks synthesize all sorts
of patterns (the idea is to null out interfering stations) by
combining the signals of different antennas of various types, from
loops to Beverages. One can, for example, take a Beverage with a
minor lobe pointed in an undesirable place and null out the unwanted
lobe by phasing in a little signal from a loop. The antennas need
not be small, although phasing works best when the antennas are so
close to ground level (as at MW) that only the vertically polarized
signal component is significant.

My many professional engineer colleagues, many of whom take a back seat to no one, and a vast array of engineering literature, use inductive and capacitive. Thanks for telling us that we "may" do that. I am sure that all of those nice (but probably very commonplace) folks will be glad to know that they have the permission of an authentic *physicist*.

It's in the *standing* wave that energy is passed back and forth. The
standing wave is a reactive thing with a zero Poynting vector.

You can use most any schematic capture to plot to a file in HPGL format.
This file can be read into a word for windows document and viewed.
There
are also other programs that can read HPGL.
Or you can convert it to PDF format and send it that way. Acrobat
reader
is free.

4237. Problems with 4-1000 on 17m

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-18 00:00:00 UTC
From: Svein Henriksen <la3pu@sn.no>
Message-ID: <33586C0B.6FC6@sn.no>
Source record: 94816

Just finished an amplifier using a single 4-1000 with 4500v on the
anode. It works greate on all but one band frm 160 including 10m. On 17m
it is not possible to get it running. There are no parasitic ocillations
but i suspect that it may be ocillating on the operating frequency. I
have grid current flowing so its taking drive. Some power output is
indicated on the power meter, but IC is way to high wit only a 15 to 20
watt drive and the tube gets red hot in seconds. It is not possible to
dip the IC with the plate cap. The anode choke does not get warm so
there are no series resonances there. The configuration is grounded
grid. Drive on the cathode. I am still working on the problem and have
not given up, but any suggestions would be highly apreciated.
Thanks in advance.

You think I'm a physicist? I'll have to tell my boss: he can't figure out how to categorize my job that precisely :-).

The terminology is the same in engineering. I've never seen any reference to "inductive" or "capacitive" antennas in the engineering literature, but I've certainly seen "electric" and "magnetic" antennas, Hertz vectors, multipoles, etc.

In referring to EMI, the engineers I work with use "electric" and "capacitive" interchangeably (also "inductive" and "magnetic").

The main differences seem to be that many physicists prefer Gaussian units, in which Maxwell's equations are a bit simpler (none of this epsilon naught and mu nought stuff, just c), but the 4 Pi's show up in counterintuitive places. Also physicists tend to think of B as the "fundamental" magnetic field, and "H" as the derived one, EE's like it the other way (I have no opinion, seems unimportant, although I got in the habit of using B in grad school).

baggybobs' buck a bag bargain bonanza
brought to you by bob & kim.

all new surplus unless otherwise noted

Shipping to the USA
Small parts orders (less than $35 usd). I ship by priority mail. Cost is $3

Larger parts orders I will ship by UPS using an agent. Cost is $5
I ship UPS COD only upon receipt of $10 deposit. The UPS depot is 60 Km
away. I have to drive there and handle CODs myself. I cannot afford the
cost or hassle of refused COD shipments.

Really small parts orders (up to $5 surface mount parts only). Send me a
SASE with three stamps. I will put in some foam filler to prevent damage.
International orders require international money order or funds drawn upon
a US bank. We can determine together the best way to ship.
.
If you have tech questions please e-mail. I will answer in a day or two.

Address:
Kim Kelly
507 Broad St
Apt 144
Lake Geneva, WI 53147

Hirose microphone plug. Used on many imported HTs $6 ea
Hirose # SR30-10PE6P 6 pin plug with threaded lock. Has 5 notches on shell for indexing. Look in Digi-Key catalog for picture

Motorola 6 unit rack charger-battery conditioner for STX portable batteries. Model PLN 1193A. Also for MX radio Model PLN1157A. Like new.....never put into service. Copy of manual included. $200 ea plus UPS shipping.

Motorola Intellicharger desk charger for any flip phone or Elite. Rapid charges both NiCd and NiMh batteries and then switches to pulsed "top-off" mode to prevent overcharging. Holds two batteries. Very good condition includes wall transformer. $30

Motorola Intellicharger for brick phone. Works same as above but only one pocket. $30

Switching supply plugs directly into wall socket (US or Japan). About the same size as computer mouse. Well filtered output 1 Amp @ 7.5 V or programable up to 10.5 volts using external feedback resistor. Input 100 to 240 volt. Made by Anam, Daewoo, Phihong and others but no choice because I don't know who made what. Output cord is about 4 foot long with leads at end. May have cosmetic blemishes so I'm not calling these new. $8 ea or 2 for $15.

thank you

baggybobs' buck a bag bargain bonanza
brought to you by bob & kim.

Surface mount parts for experimenters/prototypers
all new surplus unless otherwise noted

Shipping to the USA
Small parts orders (less than $35 usd). I ship by priority mail. Cost is $3

Larger parts orders I will ship by UPS using an agent. Cost is $5
I ship UPS COD only upon receipt of $10 deposit. The UPS depot is 60 Km
away. I have to drive there and handle CODs myself. I cannot afford the
cost or hassle of refused COD shipments.

Really small parts orders (up to $5 surface mount parts only). Send me a
SASE with three stamps. I will put in some foam filler to prevent damage.
International orders require international money order or funds drawn upon
a US bank. We can determine together the best way to ship.
.
If you have tech questions please e-mail. I will answer in a day or two.
Address:
Kim Kelly

The required waveguide cross section area at 2.45 GHz is about 50 cm2 and at 500 W RF power, the power density is about 10 W/cm2. If the waveguide is connected to a short horn antenna, the power densities close to the horn is about the same magnitude. The maximum recommended exposure for the uncontrolled environment (general public) is about 2 mW/cm2 around 2.5 GHz, so the exposure very close to the antenna is 5000 times too large. However, 2 mW/cm2 is 20 W/m2 so you are within limits, when the area illuminated by the beam has increased to 25 m2 (=500/20). To calculate the safe distance, you have to know the beam width of your antenna.

However, the microwave oven magnetron is a poor device for hunting birds, the power is too low and the frequency is also too low. To kill a flying birds, you need a high power density at a great distance and you can get this by using a narrower beam, using an antenna with higher gain. To get more gain, you can use a large parabolic reflector. When the reflector diameter goes up, so will the area increase, but the power density illuminating the reflector goes down. When the area in this case is 25 m2 (about 6 m diameter) the power density at the surface is as low as 20 W/m2 or within the exposure limits. In a correctly adjusted system with the radiator in the primary focus, the beam leaving the parabolic reflector has the same cross section as the reflector, increasing at the inverse square rule when the distance is increased. Thus, it is much more safe to walk near a large parabolic reflector than a small parabolic reflector if the transmitter power is the same. The most dangerous are the small horn antennas, which look innocent, but they can cause a very high power densities at short distances.

For hunting flying birds a much higher frequency is preferable, since to get a much higher power density at medium distances, much more gain is required and a larger antenna in terms of wavelengths must be employed. At higher frequencies, the physical size will be smaller and thus, the initial cross section of the beam will be smaller, resulting in a higher power density at medium distances.

> The total effect is that the shield becomes the receiving element.
> It's like you changed the diameter of the element slightly.

This is certainly true for the differential mode response of my
Kitt Peak antenna, or at least that's what my design calculations
said. I'm not, however, sure that this is true in all topologies.

> The only
> thing the Faraday shield really does is modify common mode capacitive
> coupling, something that general;ly isn't a problem anyway in a low
> impedance loop antenna.

The impedances of multi-turn tuned loops can be high, although the
builders might be well advised to bring them down by one of the
possible transformation techniques. Part of the difficulty is also
that small loops tend to be considerably less efficient than a
dipole of the same size, so the common mode output may be larger
than the differential mode.

> The "shield" only helps if direct capacitive common mode coupling
> exists to the feed system (via the loop), something that even the
> casual loop builder can easily avoid.

I'm not sure it's always as easy as you say. In any case, there
are usually two approaches to any common mode pickup problem: the
"series" approach and the "shunt" approach. In the series approach,
one attempts to reject common mode by preventing common mode current
from flowing into the system. Baluns and transformers are examples
of this approach. The series approach often works best when the
common mode impedance is low (not the case here).

In the shunt approach, one attempts to get the common mode current
to flow someplace harmless. This approach often works best when
the common mode source impedance is high. The Faraday shielding
techniques for transformers and loop antennas we've discussed are
examples of this approach.

In many years of chasing EMI problems, I've seen many more difficulties
with the series approach (which is what I believe you're advocating)
than the shunt approach. However, there are times when one or the
other is clearly better, and there a some times when you need both.
I have little experience with loop antennas, so it is difficult to
judge.

For the Kitt Peak antenna, the issue is lightning, which must
always be dealt with in shunt fashion. Tens of kiloamp pulses
can be conducted by ordinary cables, but no practical insulation
can stand off tens of millions of volts. The purpose of the shield
is thus to carry the lightning current safely to ground. Calculations
suggest that in the event of a direct strike, the antenna still
picks up substantial energy in differential mode, but the differential
current is within the capacity of a gas discharge tube (of which
there are three).

Small signal common mode rejection specs do not apply during
lightning strikes :-).

In any case, a WWV receiver has survived ten years of being hooked
up to this antenna, although the observatory has suffered much
other lightning damage in that interval. I must have done *something*
right here :-).

>mounted the camera in (2" PVC vacuum tubing) and works quite well.

While this might work normally, how does it work when the light levels
drop,
like at twilight, or dawn? I also wonder what happens if it rains and the
rain spots the lens. (I wear glasses, if I don't clean them after being
caught
in the rain, I get spots on my glasses whether they're sun glasses or not.
I must say though that your idea of the sunglass lenses might be better
than other solutions. Also, I wonder how well infra red passes through
photogrey lenses, if it does, then probably turning on an led at night
aimed at
the tower might provide almost enough illlumination. -art clemons-

After using the photogrey lens in varying light and weather conditions,
I've found that low light capability is roughly the same as with a
plain glass lens in front. Dusk, dawn and cloudy days still give a
better picture than bright sunny ones. Prior to using the photogrey
lens, sunny daylight scenes were impossible.
A perfect solution? No. However it is as good of one as I need.

We have the following CD-R media and CD-Recorders for Sale:

Brand: Pioneer
Type: Printable Media (Surface of cd is blank for printing or labels)
Type: Gold on Green
Size: 74 min (650 mb)
Price: $ 5.00
Packaging: Jewel Case
Minimum Order: 10

Brand: Maxell
Type: Gold on Gold
Size: 74 min (650 mb)
Price: $ 5.00
Packaging: Jewel Case
Minimum Order: 10

Brand: Maxell
Type: Unbranded (CD and Jewel Case is blank with no name on it)
Size: 74 Min (650 mb)
Price: $ 5.00
Packaging: Jewel Case
Minimum Order: 10

Brand: Maxell
Type: Unbranded (CD is blank with no name on it)
Size: 74 Min (650 mb)
Price: $ 4.75
Packaging: Spindled
Minimum Order: 50

Brand: TDK (IEC Nippon)
Type: Gold on Green
Size: 74 min (650 mb)
Price: $ 5.00
Packaging: Jewel Case
Minimum Order: 10

Brand: TDK
Type: Gold on Green
Type: Unbranded (CD is blank with no name on it)
Size: 74 Min (650 mb)
Price: $ 4.75
Packaging: Spindled
Minimum Order: 50

CD-Recorders

Brand: Yamaha
Speed: 4 Write X 4 Read (4 X 4)
Version: CD-R 100 Internal Version
Software: Gear 4.0
SCSI Card: Adaptec
Comes complete with All Cables and Software need for Installation.
Media: 5 Pieces of your choice
Price: $ 999.99 US

Please take note that our phone number as changed from (213) 650-1680 to: (714)-461-5150

Previously you said an electric field is not present in the inductor. Now you talk about *energy* in the inductor fields. Which do you really mean? They are not synonymous. One way to win an argument, of course, is to keep changing the subject.

> No. The the key thing to remember about an inductor is that the E
> field along the wire is *zero* (ignoring resistance). This is the
> electric boundary condition for a conductor.

It is a boundary condition for voltages due to charges. For emf's due to induction it is not true. Faraday's law is specific about that, and every reference that I have ever seen verifies it.

> Along the wire, there
> is a *potential gradient* that *cancels* the E field due to dB/dt.

A potential gradient is due to an E field. There is no such thing as a potential gradient that does not have an associated E field.

E = -del V never goes on holiday.

Conversely, without the E field there is no voltage gradient. If you start at one end of the wire, integrate the voltage gradient to the other end and then integrate the E field back to the original end, of course you get zero. That does not mean that there is no E field. It is an electromagnetically *induced* E field and also an *induced* voltage gradient. They are *completely* indistinguishable from each other.

The idea that there can be no E field in a perfect conductor is one of the most misunderstood ideas that there is. It is ridiculous. A perfect conductor is not a perfect conductor unless it is perfectly conducting, in other words a short circuit (or it extends to infinity). Then and only then there is no E field. For an electromagnetically induced voltage, a piece of wire is not a short circuit. If you slide one of a voltmeter's leads along the wire the voltage increases uniformly. Whether you call it voltage gradient or E field is totally irrelevant and I defy anyone to tell which is being measured.

> > Inside a capacitor there is a displacement current. One can easily
> > calclate an H field that is created by this displacement current.

> > Textbooks contain exercises that ask us to calculate this H field.
>
> But that H field has no appreciable influence on the dynamics of
> most practical capacitor below VHF frequencies

I never said that it did. But your statement was that the "field in a cpacitor is all electric". That was false. Changing the ground rules again.

> Have you built a
> transformer with a dipole for a secondary yet?

Baloney.

> "You can't confuse me, that's my job."

I believe that.

4254. Seeking simple SW receiver designs

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-18 00:00:00 UTC
From: jjknap@skcla.monsanto.com
Message-ID: <1997Apr18.083107.1@skcla.monsanto.com>
Source record: 94899

I have a group of cub scouts and I thought it would be nice to have
them build a simple shortwave receiver. Im looking for a design that would be
cheap to build, use commonly available parts and would be functional enough
that the the boys could have some fun using it. I can make circuit boards, no
problem. Ideally the design should not use impossible-to-find coils or any
other hard to find parts. Maybe varactor tuning would keep things simple.
Regenerative or NE602 based would be OK. Open to any suggestions.
I am quite experienced in electronics tho not in radio. Ive seen some
simple designs but most seem to have some flaw - expensive, sensitive or hard
to obtain parts etc. If anyone could direct me to some designs that they think
may fill the bill I would be grateful.
Thanks
Friendly Regards,
Jerome Knapp jjknap@skcla.monsanto.com

There is a new LISTSERV e-mail list for BOATANCHORS enthusiasts that I just discovered! The best part is that it is FREE!!
To subscribe, send an e-mail message to:

LISTSERV@LISTSERV.TEMPE.GOV

with no subject, and the text:

subscribe boatanchors <Your Full Name>

The only odd thing is that it wants you to send you name with a middle initial otherwise it rejects the subscription.

For example, I had to send:

subscribe boatanchors Brian J. Carling

See you there!

>>Do you know why they called it class E, or what the textbook
>>definition of class E is???
>
>i believe the difference is C exhibits some degree of linearity, while
>E is a completely saturated switch. moot point ,imho.

Here are some definitions from one textbook...

The following is from SOLID STATE RADIO ENGINEERING, by Krauss,
Bostian, & Raab, Chapter 14 "High Efficiency Power Amplifiers."

in the chapter's intro:

"In 'switching-mode' PAs this (increased efficiency - Jeff) is
accomplished by employing the active devices (BJTs, FETs, or vacuum
tubes) as switches rather than as current sources. Since an ideal
switch has either zero voltage across it or zero current through it at
all times, it dissipates no power. Other high-efficency PAs (Classes
F, G, and H) use special circuit techniques, including harmonic
resonators and multiple power-supply voltages, to reduce the collector
voltage-current product."

Later in the text...

"A Class D amplifier employs a pair of active devices and a tuned
output circuit. The devices are driven to act as a two-pole switch
that defines either a rectangular voltage or rectangular current
waveform. The output circuit is tuned to the switching frequency and
removes its harmonics, resulting in a sinusoidal output."

And still later...

"A Class E power amplifier employs a single transistor driven to act as
a switch and connected to a passive load network. The
least-complicated load network consists of a series tuned circuit
connecting the collector to the load and a capacitance C shunting the
collector to ground." (This is identical to the topology in Fig. 3 of
the QST article).

Later yet...

"Class F is porbably the oldest practiced method of improving PA efficiency, and is also known by such terms as 'biharmonic,' 'polyharmonic,' 'Class CD,' 'single-ended Class D,' 'high-efficiency Class C,' and 'multiresonator.' A Class F amplifier is characterized by a load network that has resonances at one or more harmonic frequencies as well as at the carrier frequency. The active device usually operates primarily as a current source or a saturating current source, as it does in the Classical Class C PA. (The authors place Tyler's amp in the Class F category)

There's also this warning: "The reader is cautioned that these terms (classes D, E, F, G, H, and S - Jeff) are not universal; in particular, the terms 'Class D' and 'Class S' are often reversed or used interchangeably by other authors."

- Jeff, WA6AHL

A lot of newcomers may or may not know this. Hell, they may not know
hat a FAQ is, or where to look. The title of the group should be
rec.radio.amateur.equipment.discussion or something similar. If you
were new, and saw the title as it is now, wouldn't you think this is
the place to sell equipment? Also some servers may or may not access
all the groups.

On the subject of "noise level", some would think that the HRO and cat
pee threads, as well as old what's his name the teacher (Who
thankfully has been absent of late) might well be considered noise
level by many.

It would be a simple matter to set up a killfile for any ads
containing "FS, WTB",. etc.

4263. www.hamradio-online.com: FCC Allows High Gain Unlicensed Tx in Amateur UHF Bands

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-19 00:00:00 UTC
From: vbook@vbook.com
Message-ID: <5jbjs0$f5o$1@kanga.accessone.com>
Source record: 94758
Cross-posted to: rec.radio.amateur.misc,rec.radio.amateur.digital.misc,rec.radio.amateur.policy,rec.radio.amateur.homebrew

Under terms of the Report and Order in ET Docket 96-8, released April 10, 1997,
the FCC has announced that it will allow high gain antennas
for unlicensed transmitters operating in the 2400 and 5800 MHz
Part 15 allocations. These bands are shared with the Amateur Radio Service.

Under the new rules, very high gain antennas may be deployed at 2400 and
5800 MHz. Certain transmitter power reduction restrictions apply at 2400 MHz
but unlimited gain systems may be installed at 5800 MHz. These systems will
enable high speed Internet access using unlicensed systems. You can expect to
see these systems deployed rapidly as soon as 1998 to provide non-commercial
and commercial services on these frequencies.

The complete story, including the Report and Order, is now available online at:

http://www.hamradio-online.com

I recently installed an Icom 706 in my pickup. I operate mostly on 75 meters with the antenna either mounted on the bed of the truck or on top of our cab-over camper. I have been less than thrilled with the Hamstick antenna I have been using, and have heard good reports on the "bug catcher antenna". I assume this to be a center loaded unit with a large (high Q) loading coil. Can anyone tell me where to obtain one of these antennas or find design information so I can build one? I would be interested in hearing of experiences with the bug catcher or any other 75 meter mobile antenna. Does anyone know if B&W Mini-ductor is still available and where it can be obtained?

Well, I have finally gotten around to joining in on this most worthwhile discussion. I've been experimenting with multi-turn electric field loops for a while now, as well as the problem of remote tuning and active antenna amplifiers. Therefore...

John Doty <jpd@space.mit.edu> wrote:

: The impedances of multi-turn tuned loops can be high, although the
: builders might be well advised to bring them down by one of the
: possible transformation techniques. Part of the difficulty is also
: that small loops tend to be considerably less efficient than a
: dipole of the same size, so the common mode output may be larger
: than the differential mode.

Less efficient, yes. But, if the length of wire in the antenna as about 3/4 wavelength, the efficiency approaches 80%. At 3/8 wavelength, this decreases to 40% at best. Most loop antennas being used have a total wire length of less than 1/4 wavelength, at which point the efficiency is less than 5%. These numbers are well documented in several professional papers, if anyone is interested.

: I'm not sure it's always as easy as you say. In any case, there
: are usually two approaches to any common mode pickup problem: the
: "series" approach and the "shunt" approach.

<*** TERMINAL SNIPPING ***>

I have stuck with the "shunt" approach, tuning the antenna with either a parallel capacitor or inductor, more often the latter as remote tuning can be easily accoplished with a transductor (saturated reator) which will not generate harmonics or intermodulation at "normal" signal levels.

The even-mode EMI problem is overcome by designing a properly conditioned first stage of amplification, employing common-node feed back to eliminate the common-mode signals, as well as any second harmonics from the amplifier. The amplifier quickly becomes the Achilles Heel in an active antenna design, and I am using some unusual feedback techniques (lossless feedback and current-sourced bootstrapping) to ensure that the intermodulation is kept under close control. Most of the amplifiers that I have seen fail to adequately address this issue, although I will admit that I have not seen anything.

A previous posting in a similar thread mentioned using GaAs FETs
in the antenna amplifier, which I agree with. The follow-up postings
were mostly concerned with noise figure, and I don't believe that the
issue of intermodulation was ever brought up. If it was, I missed it.
GaAs FETs can give very good intermodulation performance, particularly
the NEC NE25339 Dual-Gate GaAs FET when the second gate is connected to
the source (Vg2-s = 0.0). It is also very easy to bias, being a deple-
tion mode device. Philips makes a Dual-Gate MOSFET, the BF990, which
will deliver similar performance, although the biasing requirements are
somewhat more demanding due to it being an enhancement mode device.

The final design for my antenna is still in the works, and when
it is finished I hope to submit an article to Communications Quarterly
for publication.

I gotta go.

A superregenerative receiver would be perfect. With a good design, you should be able to cover 0.5mhz to 400mhz with plug in coils. With switched coils maybe 0.5mhz to 100mhz.

My first shortwave listening was done with a Radio Shack kit bought in the early 70's. Using only 3 transistors and superregenerative detector, it was plenty sensitive enough.

Rob.

Marty, what is getting bad? Is the equipment getting bad and hams want
to sell it? Is the introduction of new radios getting so bad that hams
have to sell their 4-month old "state-of-the-art" stuff to buy this
weeks Yae-com-wood intruduction? Maybe we should just buy radios and
not sell them - like guns, you can never have too many!
I would rather see folks selling stuff than the inane "whats the mod (so
I can transmit on COP frequencies or listen to cellular phones) posts?
And let us not forget the "Teddy Bear" posts that just wouldn't stop.
So, gosh, someone is trying to sell a radio. Should we also be
concerned that others are trying to find or buy, as in WTD and WTB,
radios as well?
I'll probably feel a little guilty for responding to this, but sometimes
you feel like a nut...

4269. Re: BEST Active antenna design in the world!

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-19 00:00:00 UTC
From: jpd@space.mit.edu
Message-ID: <5j91ur$hf8@senator-bedfellow.MIT.EDU>
Source record: 94822
Cross-posted to: rec.radio.shortwave,rec.radio.amateur.homebrew

Enough theory and disagreement, how about some real data:

I have compared the EMI response of two different antennas directly attached to my Drake R8 receiver. One is a 4 foot vertical whip attached to the high impedance input, and one is a loop 8 feet in circumference, oriented in a vertical plane (more or less), attached to the low impedance input. These sizes were chosen because they are small and because (by experiment) their response to broadcast signals around 1 MHz is approximately equal.

The receiver sits on my desk, between my computer and my printer.

WBZ on 1030 kHz reads about S8 on either antenna.

There is a strong EMI signal at 1020 kHz on the loop antenna, about S7. On the other hand, this signal barely twitches the S-meter on the whip antenna. Moving the whip around, I can tell this signal comes from the printer (right rear corner, in fact). One "S" unit on the Drake is supposed to be about 5 dB: I've checked it previously and it's a bit less at the low end. Nevertheless, the difference in the pickup of this EMI between the two antennas must be something like 25 dB.

Given that the measurements themselves were performed in a space of a few thousandths of a wavelength, this must be about the purest magnetic field you might ever expect to encounter at RF!

This particular narrow band EMI is nearly the strongest thing audible on the loop in the vicinity of 1 MHz. Many other narrow band EMI signals and much broadband hash are audible on the loop. Little of this is audible on the whip.

There is, however, a buzz at 960 kHz that is S2 on either the loop or the whip. This is not coming from the computer or the printer (turning them off makes no difference). It is also, however, not radiated energy: it is inaudible on my outdoor antenna (there's a big pileup of broadcast signals in its place). Grounding the receiver to the outdoor antenna's ground system reduces the strength of this signal on the whip a bit. All these characteristics suggest that this is common mode EMI coupled through the AC line. I do not know where it originates.

At higher frequencies it is more difficult to be quantitative because there are no steady broadcast signals to cross calibrate the antenna responses accurately. Fading is a real problem. Nevertheless, I can report a few things:

Most of the EMI at my desk comes from my computer.

In this EMI field, the loop yields a poorer signal to noise ratio than the whip in most cases. However, this effect decreases with increasing frequency. By 10 MHz, it is noticeable, but not large.

Above 10 MHz, the EMI pickup on either indoor antenna is so large that no broadcast signals are audible as comparison standards.

Conclusions:

The computer EMI is nearly as purely magnetic as physics allows, given the distance and frequency. Electric and magnetic energy are balanced in the 960 kHz EMI, which appears to be common mode. No predominantly electric field EMI was seen.

Loops are no miracle cure for EMI. On my desk, a loop is the *worst* possible choice. Nevertheless, there is a choice to be made, and it can make a difference. The difference is greater at lower frequencies.

The only sure cure is to get the antenna away from EMI fields, together with precautions to prevent common mode from conducting the EMI to the antenna.

> increase, but the power density illuminating the reflector goes down.

But it's difficult to rapidly move the large parabolic antennas, and they must be build very ruggedly to withstand the high accelerations that you will need to track the bird (since your beamwidth is small). Also, once you try this you will find you need to be able to move your feedpoint so that you can focus the 2nd focus point not at infinity but at the range of the target bird.

In the end, the cost of the magnetron is small compared to the rest of the system, so, yes, you are right that this is an inferior bird hunting system.

The big question -- Why is the impedance
so critical? What kind of stop bands and slope factor are you looking
for?

If you can live with a 13-kHz bandwidth, and are willing to add some
matching circuits, surplus fm receiver filters should be relatively cheap.
I think they are bit lower in impedance than 3.3K-ohms, though.

I would place a want ad in this newsgroup with the exact filter specs.
you need and I will bet you are flooded with replies. If I can be of
any further help, drop me a reply.

In EE-land the SI (MKS) system works very nicely and fits in with henries, farads, ohms, volts-per-meter, farads-per-meter, amperes-per meter, ohm-meter, henries-per-meter, circuit design, EM fields, waves, filters, transmission lines, the Z0 (377 ohms) of space, and what have you. And it all ties together smoothly and consistently.

Inductive coupling, capacitive coupling, electric fields (E) and magnetic fields (H) get the delineation and uniqueness that they need in order to prevent the kinds of misunderstandings that we have seen here.

My favorite EM text is Kraus "Electromagnetics" 4th edition 1992 and he makes it all consistent with SI (MKS) units. Getting basic principles into the bone marrow is tough enough without having to go through a lot of gymnastics about units and unit conversions.

After going the route of used, surplus, etc. 'scopes, andd having them
break down after 6 months to a year, and the required parts no longer
available, I looked at what these "bargains" had really cost, and
decided to buy an inexpensive new 'scope.

I suggest you contact C & S Sales 800-292-7711. What you are looking
for will probably cost you $500-$1000 but it will be worth it to get a
NEW 'scope with warantee, etc.

Sounds like the anode is not hitting resonance, and the anode
impedance is very low..

>The anode choke does not get warm so
>there are no series resonances there.

There still might be a series resonace there, even though it does not
get hot. Did you check the choke for series resonances??

>The configuration is grounded
>grid. Drive on the cathode. I am still working on the problem and have
>not given up, but any suggestions would be highly apreciated.

The only other thing I can think of is an unwanted series resonance in
the tank. Did you check the tank?

On occasion we can have a high impedance presented to the cathode by
the input at the odd harmonics of the excitation, and that will cause
a large efficiency reduction, but that does not fit your description.

I assume you have a conventional system with the grids grounded
directly and no idiotic trick circuitry in the grids??

A few years back a tornado devestated part of Plainfield, Illinois.
Many amateurs volunteered for emergency communications. I spent a day
assigned to the Will County Sheriff's command headquarters that was
the overall command post for the relief effort. Three different
times an officer told me that without the hams, they would NOT have been
able to do their jobs; we were the only communicators who could provide
communications between ALL agencies involved. Also, those with cell
phones learned they don't work well after the cell sites have been
destroyed, power has been knocked out, phone lines destroyed, etc.

In emergencies and disasters, many agencies are involved: local, state
and federal agencies, the American Red Cross, the Salvation Army,
private
business (someone has to provide fuel trucks for generators, food for
victims and volunters, etc.) and many others. We amateurs are in a
unique position as we are the ones able to provide personnel with
radios to all those involved enabling every agency/group/business to
communicate with everyone else. Technology will not eliminate our
importance to emergency communications.

Thanks to Gumm for an excellent note on his design.

Now look at Communications Quarterly, Winter 1996, p 47. (Reprinted from a talk a RF Expo, East, 1994 and RF Design)

After you manage to work through the references to wrong Figures and cryptic language and a noticeable bias toward using modern integrated circuits, you find that "According to our simulation analysis, both circuits only provide +4 dBm. We weren't able to confirm the +17 dBm measurement reported by the authors."

Well, as I've commented before, every model I've built from the original Hayward book gave an output similar to that published. In this case I'll go with the solder data. (And for anyone interested, somewhere in my large junk box is an all-pass filter for the input of a Dentron MLA-2500, built from a Ham Radio Magazine article, that would have worked better if built totally out of solder!)

yes, indeed!
I believe it is the time to look for something new, LCD scopes from
Fluke and others are reasonable priced, and will work upwards 100MHz,
but of course if you are making bad soldering inside you should look for
some old rubbish

Yeah, I also built one of those for my first foray into SMT. Hot Damn, and it works, too!

I've got terrible nerves and the SMT was a little nerve-racking. I'd suggest you clean your glasses (you WILL need them!) and inspect each joint with a jeweler's loupe before going to the next. Be especially careful with the SMT chips so that you don't bridge any contacts. That happened to me and the VFO didn't work the first time out. Another inspection found the bridge. A quick hit with a solder sucker and I was in business.

Does anyone have plans for a 2m rig similar to the Ten-Tec kit but with 50W. I'd like to built a 2m rig from scratch. I need a schematic and parts list with specs and all. I need a good radio design with parts I can buy from Digi-Key or the like. I would like to keep parts as low price as possible. Has anyone ever done this? I am interested in your unfinished kits too. Please EMAIL me.

Try posting this in the HEATHKIT USERS E-mail list!!

Here's what I have:

From: "L-Soft list server at LISTSERV.TEMPE.GOV (1.8c)"
<LISTSERV@LISTSERV.TEMPE.GOV>
Subject: You are now subscribed to the HEATH list
To: Brian Carling <bry@mnsinc.com>
Send reply to: HEATH-request@LISTSERV.TEMPE.GOV

Tue, 25 Mar 1997 06:00:30

Your subscription to the HEATH list (Heathkit Owners and Collectors
List)
has been accepted.

Please save this message for future reference, especially if this is
the
first time you subscribe to an electronic mailing list. If you ever
need
to leave the list, you will find the necessary instructions
below.
Perhaps more importantly, saving a copy of this message (and of
all
future subscription notices from other mailing lists) in a special
mail
folder will give you instant access to the list of mailing lists that
you
are subscribed to. This may prove very useful the next time you go
on
vacation and need to leave the lists temporarily so as not to fill
up
your mailbox while you are away! You should also save the
"welcome
messages" from the list owners that you will occasionally receive
after
subscribing to a new list.

To send a message to all the people currently subscribed to the
list,
just send mail to HEATH@LISTSERV.TEMPE.GOV. This is called "sending
mail
to the list", because you send mail to a single address and
LISTSERV

makes copies for all the people who have subscribed. This
address
(HEATH@LISTSERV.TEMPE.GOV) is also called the "list address". You
must
never try to send any command to that address, as it would be
distributed
to all the people who have subscribed. All commands must be sent to
the
"LISTSERV address", LISTSERV@LISTSERV.TEMPE.GOV. It is very important
to
understand the difference between the two, but fortunately it is
not
complicated. The LISTSERV address is like a FAX number that connects
you
to a machine, whereas the list address is like a normal voice
line
connecting you to a person. If you make a mistake and dial the FAX
number
when you wanted to talk to someone on the phone, you will quickly
realize
that you used the wrong number and call again. No harm will have
been
done. If on the other hand you accidentally make your FAX call
someone's
voice line, the person receiving the call will be
inconvenienced,
especially if your FAX then re-dials every 5 minutes. The fact that
most
people will eventually connect the FAX machine to the voice line to
allow
the FAX to go through and make the calls stop does not mean that
you
should continue to send FAXes to the voice number. People would just
get
mad at you. It works pretty much the same way with mailing lists,
with
the difference that you are calling hundreds or thousands of people
at
the same time, and consequently you can expect a lot of people to
get
upset if you consistently send commands to the list address.

You may leave the list at any time by sending a "SIGNOFF HEATH"
command
to LISTSERV@LISTSERV.TEMPE.GOV. You can also tell LISTSERV how you
want
it to confirm the receipt of messages you send to the list. If you do
not
trust the system, send a "SET HEATH REPRO" command and LISTSERV will
send

you a copy of your own messages, so that you can see that the message
was
distributed and did not get damaged on the way. After a while you
may
find that this is getting annoying, especially if your mail program
does
not tell you that the message is from you when it informs you that
new
mail has arrived from HEATH. If you send a "SET HEATH ACK
NOREPRO"
command, LISTSERV will mail you a short acknowledgement instead,
which
will look different in your mailbox directory. With most mail
programs
you will know immediately that this is an acknowledgement you can
read
later. Finally, you can turn off acknowledgements completely with
"SET
HEATH NOACK NOREPRO".

Following instructions from the list owner, your subscription
options
have been set to "NOFILES REPRO" rather than the usual LISTSERV
defaults.
For more information about subscription options, send a "QUERY
HEATH"
command to LISTSERV@LISTSERV.TEMPE.GOV.

Contributions sent to this list are automatically archived. You can
get a
list of the available archive files by sending an "INDEX HEATH"
command
to LISTSERV@LISTSERV.TEMPE.GOV. You can then order these files
with a
"GET HEATH LOGxxxx" command.

This list is available in digest form. If you wish to receive
the
digested version of the postings, just issue a SET HEATH DIGEST
command.

Please note that it is presently possible for other people to
determine
that you are signed up to the list through the use of the
"REVIEW"
command, which returns the e-mail address and name of all
the
subscribers. If you do not want your name to be visible, just
issue a
"SET HEATH CONCEAL" command.

More information on LISTSERV commands can be found in the
LISTSERV
reference card, which you can retrieve by sending an "INFO
REFCARD"
command to LISTSERV@LISTSERV.TEMPE.GOV.

I hope that helps!

Bry

Eind volgende week zal Repeater 2/1997 uitkomen. Repeater is een onafhankelijk tijdschrift voor iedereen die ge�nteresseerd isin amateurtelevisie.
Enkele onderwerpen uit Repeater 2:

- Een bezoek aan PI6EHV
- Theorie omtrent het ontwerpen van ringhybrids
- een 40 Watt eindtrap voor 23 cm
- 10 GHz-ontvangst met Ku-band LNB's.
- ontvangstrapporten,
- frequentielijsten

en nog veel meer leuke en wetenswaardige artikelen.

Repeater verschijnt vier keer per jaar in full/color en een abonnement kost slechts 40 gulden per jaar.

This is actually a good thing.

First semantics, in a physics sense there is no such thing as a "gain
antenna" the best an antenna can do for you is to reshape the pattern
putting more of the energy radiated into a smaller cone.

A very high "gain" antenna directs most of the radiated energy towards
the intended receiver lessening the chance for inadvertant
interference. The long and the short of it is this order is to the hams
benefit. We will also benefit from the research and engineering that go
into these systems.

Hi all,

I wonder if someone could please help.

I have just read the March 97 edition of "Elector Electronics" and it features an eprom programmer that looks easy enought to build.

It has some the controll software "prommer.exe " from the cd rom "Elektor software 96-97" and they mention a slightly different version on a cd rom entitled " competition cd rom" complete with pcb diagram.

These are very hard to obtain in Australia and I would be very grateful if someone who has either of these cd's would please be kind enough to e-mail me a copy of either of the above if possible.

Also has any one built this and what success have they had with it ????.

Thanks,

Rob Payne VK5PR

>Thanks
>Jim WA1GPO
10.7 MHz crystal filters are the most easily available of all. OEMs only
pay a few $ for them, you dont state the stop band you require at 5kHz
however 7 pole will give excellent results.
The 3k3 termination is critical as the termination impedance is part of
the design of the filter. try to get the termination cap right also.
Watch out for breakthrough take great care with ground planes as many
filters capable of 70db stop bands only achieve 40db because thr radio
designer never got the ground plane right.
Narrow band Xtal filters have a lot of group delay a small amount of
ripple varies the phase response over th pass band and really mucks up
data. If you are interested in good group delay response try this idea I
used some years ago and which is seldom implimented.
Buy 10.7MHz monolithic duals employ as many duals as your stop band
dictates, select the termination to give correct pass band then place a
gain/isolating stage between each filter.

Problem is that the FS and WTB ads in the r.r.s group are SO NUMEROUS!

A few specialized ads in boatanchors for example, are VERY welcome by
the majority of readers.

We do not want to wade through 150 ads for dual band VHF/UHF whatsits
and packet terminals trying to find a DX-100!

Why not take this thread to r.r.a.policy?

Back in the '50s, TV sets had tuners with a large rotating drum which
had silver contact points and silver fingers to contact them. One of
my first jobs as a young apprentice was cleaning the oxidation off of
them. Silver oxide may be a conductor in theory, but those contacts
were very erratic if there was much of it there. I'd clean it off.
Ordinary silverware type polish was what we used and it worked fine.

IMO, it is quite definitely bad luck to say that there are no parasitic
oscillations.
If you have grid current when the drive is removed, you may have a
parasitic oscillation. You can check for a parasitic oscillation with a
neon lamp connected to the end of a plastic rod. Bring the neon lamp near
the anode. If the energy is at 17m, the light will be orange. If the
energy is in the VHF range, the light will somewhat purple.
>It is not possible to

True.....If the choke was the problem, at this power level, you have had a
choke fire.

Are you shorting the unused turns in the tank L?

Wow! Too many Steves here!

I think I get your point. My Motorola flip phone's pull up 5 inch
antenna would work as a long wire on some frequency. However, that's no
reason to call it a long wire. In fact, it would be kinda silly, don't
you think?

Let me quote from the A.R.R.L. Handbook, Thirteenth Edition, page 165,
the chapter entitled "Long-Wire Antennas".

"Since a wire is not "long," even at 28 MHz, unless
its length is at least equal to a half wavelength
on 3.5 MHz, any long-wire antenna can be used on all
amateur bands that are useful for long distance

communication.

As between two directive antennas having the same
theoritical gain, one a multielement array and the
other a long-wire antenna, many amateurs have found
that the long-wire antenna seems more effective in
in reception."

Note three things from this: (1) A wire must be approximately 134 feet long to be called a long wire below 30 MHz. (2) A long wire is directive. (3) A long wire has gain in reception.

If you're interested in gain figures from end fed wires of any length, see page 27-9 of Reference Data For Radio Engineers, Sixth Edition.

This discussion started when I read a note from SQ that he was thinking of replacing his "longwire" with a dipole to get better performance. Sine a long wire reputedly has gain over a dipole, this sounds funny to me. I feel certain that he was calling a random length of wire a long wire without being aware that there is a difference.

By the way, I am also Steven_Mann@UNCG.EDU. Our news server is down for repairs at the university so I'm replying from home this time!

Actually, the water absorption frequency is around 22 GHz.
But, this frequency is much too high for an effective
microwave oven, since this wouldn't cook deeply enough.

Microwave ovens are typically designed for 2.45 GHz, though
the older ones were around 900 MHz. Politics typically
determines the precise frequencies (Not in My Back Yard).

People have successfully used frequencies as low as 2 meters
for cooking hot dogs and hamburgers.--Zack Lau W1VT zlau@arrl.org

Signetics/Philips used to have an app note with code examples for this some
time
back. I have also seen examples on the net, in micro newsgroups, and on
some
of the programming CD-ROMs.

If that search fails, look at the Motorola uPs, they certainly have that
code. But
you will have to rewrite for the 8085.

Hi Cec - I'm reading your remark on r.r.a.boatanchors, and as I recall,
the charter for .boatanchors does allow for BA ads.

I wonder who the goofball was (M.A. maybe?) who originally included so
so many newsgroups? Neither .misc nor .homebrew have a problems with
lots of ads - only .equipment does, so followups should be directed
just to that group.

Boy, are you asking for trouble. Not only will the steel wool ruin
the silver plating, but you could leave hundreds of tiny steel fibers
on the coil and inside the equipment. If you feel the need to use an
abrasive around electronic parts, use Scotch Brit, not steel wool.
This includes cleaning PCB's before stuffing.

As Rich points out, the ads here are a violation of the non-*.swap
group charters.

I suppose that those who want the ads here could file the needed
actions to get the charter changed, but I doubt that will ever
happen... If they are too complacent to post in the appropriate
groups, it is doubtful that they will bother with the paperwork.

Just did a little checking of a number of the inappropriate WTB and
For Sale ads being posted...

Most are being cross-posted to rec.radio.swap and/or
rec.radio.amateur.swap as well as spamming them to the wrong groups.

Seems that the idea of the *.swap groups not being on someone's server
just don't hold water.

A friend of mine is looking for instructions to build a small
2m transmitter. The transmitter should be as small as possible
and use the leas power possible. He would like to attach it
to the collar of his cat and dog and e able to follow them
around with a mobile 2m receiver.

Has somebody a source for suitable schematics ?

I thought of an quartz-controlled oscillator and a cmos
circuit turning it on for 1s every 3-4s. But i don't know
were to find a quartz of the correct frequency (2m HAM band).

Thanks Markus

That was my post, RE: GaAsFET. I'm leaning away GaAsFETs at an
outdoor location right now as they are much more static-sensitive than
JFETs, and , and the noise figure is probably not enough better than a
quiet JFET to matter at HF (I'm thinking of using a J310 low-noise
N-channel JFET, 1.5dB NF at 450Mhz) to justify the extra cost and
difficulty of the slightly-quieter MOSFET. I keep thinking of all the
posts of people who have blown (MOS)FETs in their radios!

Now you bring up a new issue -- namely IMD (and implicitly, dynamic
range considerations.) I've heard that FETs are better than bipolars,
in general, for overload resistance, but are you saying that GaAsFETs
are superior to standard junction FETs in this regard? And if so, is
it "a lot" better -- knowing that's a subjective questions?

Do you have any opinion on dynamic range of a good VHF/UHF JFET
such as the J310 in comparison with a good GaAs MOSFET (I was using
MRF966, BF(R)998, etc.)?

Thanks for any feedback you have.

I've heard of superregenerative receivers for use on 27 MHz, but never seen them described for use on the lower frequencies. I'd imagine their selectivity wouldn't be much good, and they would not be able to resolve SSB/CW signals (as is possible on a regenerative set). Also there is the possibility of their oscillations causing interference.

For casual SW listening, a regenerative receiver would be OK. If you're more interested in the amateur bands, it's hard to go past a good direct conversion receiver (NE602 mixer, transistor VFO, 741 audio, LM386 audio) - this provides good SSB/CW reception and can cope with strong signals better than a regenerative set. It would also be easier than a regen receiver to make stable, and it's easy to add a CW or DSB transmitter to a DC receiver if required - this can't be done with a regen or super regen receiver.

Yes indeed. I touch on that in the story that I wrote on this. Directional antennas can and are used to minimize interference. Also, as I note in the story, the 2.4 GHz band is home to consumer microwave ovens which are a source of significant interference already. The one issue this does change is that unlicensed operations would now be likely to use external antennas, putting their signals out into the real world, as compared to typical unlicensed operation using "low level" antennas inside buildings. The most likely scenario is an increase in the noise floor in the 2.4 GHz and 5.7 GHz allocations. More troubling, perhaps is that we can expect many commercial systems to use these bands for microwave links (look at the list of who filed comments) due to the expected much lower cost of just setting up a link without the costs of licensing and the engineering, environmental and RF safety studies required to apply for a licensed link. On the plus side, more gear would be available for use by Amateurs in these bands.

GaAsFET is not necessarily any more or less sensitive than a JFET
and is definately less sensitive than a MOSFET to ESD (electrostatic
discharge). You can protect against any ESD from harming these devices
simply. The voltage input from the antenna is less than 700mv, correct?
The voltage required to damage these devices is much greater than 700mv,
also correct? Just stick two high-speed rectifier diodes, capable of
conducting forward several amperes of current, back to back, and you are
protected. All voltages exceeding 700mw will be clipped thusly.

(defined: connect two rectifiers, parallel, in opposite polarity, shunt
to ground so that regardless of the signal polarity, any voltage into
the gate of the device exceeding 700mv will be shunted to ground.)

>
> Now you bring up a new issue -- namely IMD (and implicitly, dynamic

> in general, for overload resistance, but are you saying that GaAsFETs
> are superior to standard junction FETs in this regard? And if so, is
> it "a lot" better -- knowing that's a subjective questions?

GaAsFET's are better for GHZ frequencies. The only advantage of
a GaAsFET over a MOSFET or a JFET is frequency range, they support higher
frequences which ARE UNIMPORTANT to the HF amplifier design! The
advantage of the MOSFET over the JFET in the HF amplifier design is the
fact that the MOSFET has lower input impedance, thus it will amplify
weaker signals than a JFET. With proper protection, two rectifiers wired
inversely parallel, the static sensitivity of the MOSFET is reduced, so
its higher gain due to lower input impedance is enhanced.

>
> Do you have any opinion on dynamic range of a good VHF/UHF JFET
> such as the J310 in comparison with a good GaAs MOSFET (I was using
> MRF966, BF(R)998, etc.)?
>
> Thanks for any feedback you have.

Use any MOSFET with diode protection. HF is not that fast, max frequency is 30Mhz which is a crawl today. :) I always use the most for the least myself, and my RF amp on my loopstick employs a MOSFET transistor, what ever the TO92 device that Radio Shack sells.....sq

I don't know about silver oxide, but the black stuff on exposed silver is
more likely to be silver sulfide. Its resistivity is about 2 mohm-m, or
about 100,000 times as resistive as copper. A thin coating of this probably
wouldn't adversely affect a conductor carrying RF, but you wouldn't want it
as a surface film on contacts carrying zero or very low current. That's why
low-current contacts on quality switches and connectors are gold, not
silver. (Contacts carrying considerable current clean themselves by burning
through the surface layer.)

My experience, having built and measured dozens and dozens of
transmitting and receiving loop antennas for medical and
communications use, disagrees with yours.

Total wire length has very little to do with efficiency, and I would
bet money you could never get 80% efficiency with a small (less than
05 wl diameter) loop.

It is the physical area of the loop and overall surface area of the
conductor that determine efficiency, not the number of turns.

If you had 80 percent efficiency, you wouldn't be using a
pre-amplifier.

George is absolutely right...keep the steel wool off the workbench
and away from equipment. Meter (unsealed) and speaker magnets attract
it, it gets picked up by fan intakes and is a general nuisance because
you can't see it. When I was in engineering school, we had a lab TA
that would throw you out and give you an "F" for the day if he saw steel
wool in your toolbox. If you have to use it, do it outside and clean
everything thoroughly, including your clothes.

I built a 4-1000 amp last year and had this problem on 10mtrs.
I was using a roller inductor. I solved the problem by shorting
a couple turns on the inductor.

The problem with a roller inductor is at high frequencies
you are using only 1 or 2 turns with the other 20 turns of inductor
essentially opencircuited. This additional L resonated at 10mtrs
(in my case) presenting a very low impedance to the tank circuit.
It worked fine on 12mtrs.
If you are using a bandswitching scheme you must short unused turns to
avoid this problem.

Very, very true, George. Steel wool should be avoided like
a plague in any electronic equipment. The Scotch nylon pads are
best IMEO, with care. The white variety is the least abrasive,
green is much coarser, and black is _very_ coarse. There may be
intermediate grades, too, that I'm not aware of. Some are difficult
to find.

Yeah, a lot of designs do this, and there is a huge problem - those
diodes effectively mix any strong signals present at the antenna
input and the mixing products will be radiated out the antenna.

In other words, diodes strapped across an antenna input are an
intermod factory just waiting to happen. Even at a residential
location, enough RF can be present to generate RFI, and receivers
with front-end diodes are *very much* unwelcome in commercial
radio sites.

I have searched for the KWM-380 noise blanker board and speech processor board for almost a year now, it seems they cannot be purchased any more. It is just impossible.

Therefore I am planning to build these boards from scratch for my KWM-380

I would like to keep them as close as possible to the original, of course. For that purpose, I am looking for the original Collins documentation: schematic diagrams, part lists and PWB layout, and what else there might be.

Therefore, can any-one get me copies of the original documentation ?

Also, if there is people out there who are interested in this project and want to share the PWB board costs (and the results!) with me, please be my guest. I plan to have these (bare) boards done at a professional PWB manufacturer, which won't be cheap. So the more people we can find, the better.

Maybe someone else picked up this project in the past already. If you know that person, I would appreciate it if you send me his/her name.

Date: 1997-04-21 00:00:00 UTC
From: Radio Tech 1 <ccameron@nt.sympatico.ca>
Message-ID: <335C2F02.BB7@nt.sympatico.ca>
Source record: 94673

I have aquired a number of old Farinon SS2000 Local oscillators in the 2.0 Ghz band. They apparently can be tuned right up to 2370 Mhz, according to the manual. The crystal in in the upper 90 Mhz region and comes in a 'can' transistor style package. Does anybody have any experience with these oscillators, or where one could find some replacement crystals that will work in the amateur band? It sure would be interesting to get a 300 Channnel Analog radio on the air. Lots of bandwidth to play around with.

Regards

Chris

I have aquired a number of old Farinon SS2000 Local oscillators in the 2.0 Ghz band. They apparently can be tuned right up to 2370 Mhz, according to the manual. The crystal in in the upper 90 Mhz region and comes in a 'can' transistor style package. Does anybody have any experience with these oscillators, or where one could find some replacement crystals that will work in the amateur band? It sure would be interesting to get a 300 Channnel Analog radio on the air. Lots of bandwidth to play around with.

Regards

Chris

Good point, although the same effect might be better served by
separating the commercial gear. I am sure that the motorola guys are
as sick of sifting through the TS520's as I am of downloading 75
headers to find that 55 of them are for
trunking/sabre/jobcomm/phoenix/whatever commercial band rigs that
don't interest the average ham. How about rec.radio.commercial.swap,
and let r.r.s. pick up the rest of the SW/ham/scanner/CB/etc. gear?
Bill

Ok, it may not go in this group but I have to get the word out somehow so
I am letting you know here.

The funniest web site EVER has now officially opened using REAL AUDIO technology.

Blackout's Box
WWW.BLACKOUT.COM

You will laugh, you will cry, you will pee on yourself... you will cough up your lunch
from the intense amount of laughter you will be experiencing.

You MUST check out Blackout's Box at

http://www.blackout.com

Hear the most insane stuff you have ever heard, broadcast to your
computer instantly over the net with REAL AUDIO 3.0 which you can DL
for FREE if you don't have it already. This is not a commercial site or a business
or any other type of advertisement. It is just a very funny and very FREE site that I
want Everyone to know about. If you like Monty Python, Jerky Boys, Howard Stern,
Kids In The Hall, The State, Robin Williams, Who's Line Is It Anyway,
or anything like that - you will love Blackout's Box, there is nothing like it on the net.
Don't let the words 'prank call' scare you away.. this is no 12 year old fun, this is
intensely funny candid phone call radio drama that critics on and off the net are giving
two thumbs up.

Blackout's Box simply kicks ASS, stop whatever work you are doing,
take a break, and check it out now! Life is short - LAUGH some.

This is true, but only if you live right on top of a commercial
broadcasting antenna farm. I pity anyones shortwave reception that does!
Best way around this tho is to notch filter out the local high power
signals, which unless you live near a major antenna farm, will be no
more than just one or two filters.

>
> In other words, diodes strapped across an antenna input are an
> intermod factory just waiting to happen. Even at a residential

It has to exceed 700mv and let's say that it does, use two
high speed rectifiers in series, now the breakover voltage is 1400mv,
which should protect against intermod and mixing yet still provide good
ESD protection in RF-RICH locations.

sq

(there is _always_ a solution to a technical problem.....)

> radio sites.

I have seen a solution to this problem in a german book describing high end HF receivers (e.g. from Rohde & Schwarz). Several designs use BFT66 (or similar) transistors with their base connected to the collector. The collector/base is the anode, the emitter the cathode of the new 'diode'. If You connect the base directly, You get a very fast diode with 0.7V forward voltage drop. If You connect it via a resistor, You get some kind of a very fast Z-diode with more than 0.7V voltage drop. As mentioned by Steve, two of these are backed antiparallel, to protect the input in both directions.

I once have tried to simulate this. Results were, that, even with a resistor between base and collector, the transistor starts to conduct at 0.7V, but it is not saturated yet. I assume, that this does not avoid *all* IMD, but greatly reduces it.

Regards

Robert (HB9NBY)

4369. Panel Lettering: Datak or laser lettering?

Newsgroup: rec.radio.amateur.homebrew

Hi,

I want to letter a panel with black lettering. I have used Datak lettering in the past with good results, but now I can't find any dealers who carry Datak lettering. Anyone have their address, or know of a dealer who carries their lettering kits?

I also have a laser printer and several drawing programs. Has anyone done any transferring from a sheet designed for transfer to a panel? If so, how well did the process work, how is the durability, what sort of clear finish was applied over the lettering, etc?

Thanks, Jack WB8BFS

I agree with using Scotchbrite on new PC boards, but returning to the oriinal question I'd never use ANY abrasive on silver-plated materials.

A chemical cleaning method is by far the best solution (pun intended). Use the clear liquid which is intended for dipping small items of jewelry. In Britain it's called "Goddard's Silver Dip" but no doubt there's a US equivalent - can anybody help?

Rub the solution on gently using a cotton bud - damp, not wet - and the silver sulphide comes right off, leaving a clean surface. Wipe over with a tissue and you're done.

what you need is an old PT (potential transformer) from a 2400 volt motor controler. Call a local electrical contractor that does industrial work. Or call Westinghouse, GE, Allis Chalmers, industrial division they may be able to point you to used stuff.

Greetings, Boatanchor and GlowBug fans!

I need a small filter choke for the low B+ line in a transmitter
power supply I'm building. Something around 8 to 12 Henries at
100 mA or so should do the trick. Needs to be fairly small in
size (limited space in the chassis).

Okay guys, check your junkboxes...

PETER

I've been listing :
1 x NOS 4-1000 (this is an unused tube)
1 x used 4-1000 (works)
1 x 4-1000 socket (used)
1 x NOS filament transformer for single 4-1000
All for $200.
Have only received on good bite but it didn't sell.
Bet it would go in a minute for $100 but I'm not
selling for that :-)
Would trade toward an EFJ Navigator transmitter

Contact Kenwood.
Ask for the manual for the IF232 interface for the TS-450 radio.
They will probably charge you $10 for this manual.
It describes everything you ever wanted to know about the interface.

If you want responses, leave your email address intact.

A lot of us just won't bother to reply if we have to spend
the time locating and editing that email address ...

4378. HP COUNTER MOD 5326B

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-22 00:00:00 UTC
From: Marco Feliciotti <feliciotti_marco@alitalia.it>
Message-ID: <335D6E33.6C76@alitalia.it>
Source record: 94696

I am looking for the manual of an old HP counter mod 5326B
My counter is s/n 1139Gxxxxxx and I have a manual for s/n 1124A until
1555U but I discovered that my counter have a lot of not marginal
difference inside.
Is there anybody that knows such counter to help me ????

Message-ID: <335D14ED.6E57@qsl.net>
Source record: 94697
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc

Hello Everyone: I recently acquired an nice QRP station
from another HAM. HW-8, tuner, qrp wattmeter, speaker,
and power supply. This rig is outstanding in the 80/40
bands but somewhat less so at 20; Nothing at 15 Meters.

Using my pixie2 as a frequency spotter, I have verified
correct frequency readings on all bands but it is the only
thing I pick up on 21.120 MHz (3rd Harmonic of 7.040 xtal)
from my pixie2.

I have replaced the antenna connector (RCA) with a high
quality RF-type BNC. The old connector was intermittent.
Reception has improved slightly on all band, with an increase
in noise the only observation on 15 Meters.

I have a good compilation of articles regarding the HW-8 describ-
ing a sensitivity weakness at 15 Meters, but this is ridicul-
ous! It's gotta be better than this! I'm going to run thru
the unit with a commercial rf detecting probe tonight. (The
first 2 alignments I used a basic detecting diode as described
with the manual.)

I appreciate any help given.
TIA
-Ed Loranger

Hi:

I have been following the Lightning detection thread and am somewhat interested. To that end this past weekend I was at a scrap dealer and came across a CRT (2BP1). I have looked at my references and cannot find the specs for this tube. Could someone please help me with the following?

I would need:
1) the tube base pin description (twelve pins on base, ten of which make it into the glass envelope) and
2) the typical operating conditions (voltages, heater voltage/current, ...)

Please email the info to me, and if requested I will post the info back to the news group.

Thanks for your time.
Malcolm Latorre.

Make sure the band is really open before tearing the rig apart.

:I would like to find out any data on a B&W 852. It is a tapped inductor
:for a Pi Network, Looks like 5KV or better. Would like to know the
:rating and the inductance at the taps. This unit has a built in rotary
:switch to change taps. Thanks for the help N1DVE, Jacqui

These are really nice units. They could easily run at 5kW. I think B&W is extremely conservative in their power ratings.

I ordered mine for an 8877 linear back in 87. Took them a few months to deliver, mainly because unit was at plating shop for so long. But was worth wait. Think I paid about $120 for it back then.

They also sent along extra switch hardware and contacts. A real class act.

But, don't do what I first did before I decided on B&W: I bought one of those silver plated roller inductors using spiraling rectangular conductors. Insulation was lucite or plexiglas. On 10m the insulators started to bubble and explode like fire crackers. It might work for antenna tuners, but not in amp tanks.

Rob.

I second the idea of a regen circuit. I came across a design
a couple of years ago that I put together for fun, and I thought at the
time that it would make a great project for kids. I found the circuit
in the August 18, 1994 issue of EDN magazine, p 98. It uses 3 transistors
(2N2222's), a few ordinary diodes, one germanium diode (1N34), plus a handful
of resistors and caps. The
coil is wound on a plastic pill bottle, and it uses a small variable cap
(250pf, although I used a 365pf unit from an old AM receiver) This particular
design has a very low power regen stage, so radiation should not be
a problem if it oscillates in use. Sensitivity is surprisingly good,
even with just a short whip antenna. I fact, if you want to attach a "real"
antenna, you need to couple it very lightly into the tank with a 2-5pf cap.
The tuning was a bit fast, but managable for young hands, and I had no
problem tuning in individual stations with it.

The circuit draws less than 10mA, and should run quite a while on a 9V
battery. You could even run it off of a small solar cell array, I suspect..

Jerome, if you can't find that issue of EDN, let me know and I'll see
if I can send you a copy of the article.

Ordinary receiving GASFETs are generally somewhat better than
JFETs in regard to strong signal handling, but *power* GASFETs
are *great*, and still have a superior noise figure. (Most concerns
about NF at HF are probably in the realm of overkill, however,
atmospheric noise will dominate.)

I used to do a lot of prototyping with these, but not so
much anymore. My inactivity is your gain. I'm selling
the following integrated circuits.

17cnt 2Kx8 Static memories. Desoldered, $15
(mix of MB8128-15, TMS4016-20, TMM2016P-1/2)

Z80 Support Chips. New, $5
Z8536 Counter/Timer & Parallel I/O Unit
Z8530PS SCC Serial Communications Controller

9 8251/8251A/8251AP Program. Comm. Interface (USART). Desoldered, $18

7 8085A/AC/AH/AP CPUs. Desoldered, $16

8 8255A. Desoldered, $17

18 8212/3212 (74S412) 8-bit I/O buffers. Desoldered, $35

7 8253-5, Intel & NEC mixed. Desoldered, $15

9 Fairchild U5R7723393 voltage regulators, desoldered, $5

Prices above are flexible, but do not include shipping. I'd
like to sell groups of chips, but let me know your interest.
I'm posting this notice in several locations; please let me
know where you found it.

```
Intersil 7226-based frequency counter for sale.
Yes, it counts frequency (up to 10 MHz),
but it does more:

. intervals between two signals
. pulse counting
. ratios of two inputs
. periods of one signal

This is an un-encase 8" x 3" board, with no power supply
(requires 5 volts). Circuit is taken straight out of the
Intersil 7226 application notes, but also has an input
buffer chip.

Included is a spare 7226 (A input is fine, B input is broke),
and two spare LED digit displays.

A single 7226 itself costs $34.62 from Mouser. I'm asking
$25 + shipping, prepaid, for the whole shebang.

An electronic parts bonanza. Only nine bucks or less!

Computerized, digital, multi-line units to use as-is, or
strip for parts! They're Eagle Telephones, each with the
following, plus more.

o Epoxy encapsulated magnetic reed-switch (phone handset proximity
sensor)

o 12-button high-quality feel phone pad, about 2"x 3", with 8-wire
flat ribbon cable/connectors.

o 2" diameter, 8-ohm speaker

o Bunch of ICs: CD4081, HCF4069, 2x HCF4066, LS404CB, 2x ULN2003A,
2x ULN2032, SN75176, AMI 8948 (programmed 8048?), LM386

o 3.579575 MHz crystal

o 1.5" x 7" 20 push-button selector panel. Each button has two
colored LEDs and room to insert a small paper label. 34-wire
ribbon cable/connectors.

o 4-digit LED display, with ":" and decimals built onto the display

o Astec daughter card, 2.5"x 1.5", that appears to be a TelCo
interface

o One 4-pin, and two 6-pin J-connectors (telephone connectors,
often used on computer network cables, too).

o 8 position DIP switch

o Two 10k-ohm dial pots

o Beige enclosure. I have only a few handsets/cords. Let me
know if you particularly are interestd in the handset.

I'll sell these for $9 + shipping, prepaid. Check exact shipping
costs with the UPS web site cost calculator (my ZIP is 80840):
http://www.ups.com/using/services/rave/rate.html.

Already been done, more or less, Bill...

rec.radio.amateur.swap is for the Ham gear (non commercial)

rec.radio.swap is for everything else.

Perhaps even finer divisions are needed?

: >several professional papers, if anyone is interested.

: My experience, having built and measured dozens and dozens of
: transmitting and receiving loop antennas for medical and
: communications use, disagrees with yours.

: Total wire length has very little to do with efficiency, and I would
: bet money you could never get 80% efficiency with a small (less than
: 05 wl diameter) loop.

You obviously are not familiar with, nor interested in, the
supporting literature, which shows measured performance of 80%
efficiency at 3/4 wavelength of wire. And not just in one single
article, either.

:
: It is the physical area of the loop and overall surface area of the
: conductor that determine efficiency, not the number of turns.
:
I never said it was dependent on the number if turns. I have
repeated the literature's measured evidence that it is dependent upon
the total length of the wire.

:
: If you had 80 percent efficiency, you wouldn't be using a
: pre-amplifier.
:
At times. I don't. Most of my preamplifiers are for converting
the high impedance of the antenna to the low impedance of the cable.

If you wish to contest the measured and published data, I sug-
gest that you contact the Ohio State University's Electro Science Lab
and take it up with them. And Ronold W.P. King as well.

Regards,

Chris

As I recall, silver sulfide is pretty soft and a good banger of a relay
can clean itself. At least we are not using aluminum contacts :-)

Unfortunately these are usually 200KHz or wider. I've corresponded in private email with Sr. Garcia & he needs something narrower. Digi-Key (USA) lists Toko filters as narrow as 110KHz in their catalog. It may be possible to special-order narrower ones. (though I can't imagine what the commercial market would be)

Ah yes....but did you take the time to check his thermometer...if that
ham was already done....then sticking a fork in him would not cause a
release of air. Everybody know that only under done hams elicit air.

Oh, and some outsiders are just full of it!!!

:
: I second the idea of a regen circuit. I came across a design

If you've ever worked with kids trying to build things, you want it as
simple as possible. Especially if you are going to make 20 of them.

Regen or superregen is as simple as you can get. And the selectivity is
much better at SW than it is at VHF (native Q is already much higher in
tuned ckts)

As for radiation, you can add a broadband RF, but realize that most of
those high tech feedback circuits have little isolation as they work like
"transformers with gain" as some friends have coined. A common gate
circuit would be optimal.

A pan adapter is really a spectrum analyzer with sweep range limited
to the IF bandwidth of a receiver. It would be possible to make one
that used a o'scope for display using an NE605. The NE605 is actually
an NE602 mixer/oscillator and an NE604 limiting IF amplifier with
RSSI output. Use a varicap and sawtooth generator to sweep the
oscillator across the IF bandwith. The sawtooth will also be the
horz sweep for the o'scope and the RSSI output will be the vertical
sweep for the o'scope.

4404. ADVERTISE TO OVER 100 MILLION PEOPLE FOR FREE!!!

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-23 00:00:00 UTC
From: nejeh@gdi.net
Message-ID: <5jmd2c$65g@news.gdi.net>
Source record: 94606

Please take the time out to read this email. it is worth your time.

ADVERTISE TO OVER 100 MILLION PEOPLE FOR FREE!!!
Or send a message to millions of people...

NOW YOU CAN ADVERTISE FREE AND GET DRAMATICALLY
MORE RESPONSES THAN ADVERTISING ON NATIONAL TELEVISION

With E-mail your potential customer is forced to read at least the
headline of your letter. Unlike TV, magazines, newspaper ads, and
direct mail where more than 99.99% of the recipients will skip right
over your advertisement.

TURNS YOUR COMPUTER INTO A CASH REGISTER: Conservative estimates indicate
well over 100 MILLION people will have E-mail accounts in the next year!
E-Mail Blaster turns your computer into a cash register by giving you FREE,
immediate access to all of them. Do you think some of the more than 100
million people with E-mail addresses would be interested in your products or
services? Even if you don't have your own products or services you can
still make money buy promoting our computer software!!!
You can make money with our new software called E-MAIL BLASTER

Here's how:
* By Using E-Mail To Sell Your Products & Services
* By Using E-Mail To Sell our Computer Software such as: Email Blaster, Web Walker,
Email Lock Box etc.
* By Renting or Selling Your E-mail Addresses
* By Becoming A Distributor for e-mail BLASTER

MUCH FASTER: With bulk E-mail you get responses back in 1 to 4
days instead of waiting weeks or months like with television or print
advertising. You can begin filling orders the same day you send E-mail.

FREE ADVERTISING WORTH MILLIONS: It costs millions of dollars to mail out
millions of letters using the United States Postal Service! Now you can
send your ad to MILLIONS of people for FREE using E-Mail BLASTER

E-MAIL BLASTER IS ACTUALLY 3 PROGRAMS IN 1: E-Mail Blaster is amazing new
technology and the most advanced bulk E-mail software on the market today.
(1) E-Mail BLASTER automatically extracts E-mail addresses from America
Online, CompuServe, Prodigy, and the other online services, the Internet,
web pages, news groups, and hundreds of other sources. (2) E-Mail BLASTER
automatically stores the E-mail addresses in your computer along with
keywords that describe hobbies and interests to created highly targeted
E-mail addresses. (3) E-Mail BLASTER sends your marketing letter or ad to
MILLIONS of targeted E-mail addresses at the push of a single button!

HOW DOES E-MAIL BLASTER WORK? E-Mail Blaster has dozens of special filters to automatically harvest E-mail addresses from major online services such as: America OnLine, Compuserve, Delphi, Genie, and of course the internet.

AOL AUTO EXTRACTOR: E-Mail Blaster has many special features like the AOL Auto Extractor that let's you use a regular dial-up Internet connection to collect names and addresses from America Online. Collect America Online addresses without being a member. Allows you to download names and addresses from America Online without paying membership fees or online charges. Auto Extractor for all of the online services and Special E-mail database search engines will also be available at no additional charge.

SIMPLE TO USE: E-Mail Blaster does all the work for you. Unlike other programs where you must cut & paste addresses, E-Mail Blaster does it for you automatically. And, unlike other E-mail programs, with E-Mail Blaster there is no need to purchase any additional software

SPEED: Your time is important. E-MAIL Blaster is DRAMATICALLY FASTER at extracting and sending E-mails than all the other programs on the market that we tested it against.

NO SPECIAL EQUIPMENT NEEDED: E-Mail Blaster runs on a PC with Windows 3.xx Windows 95, Windows NT, a 386 or faster processor, 4 MB RAM, and a hard drive with at least 10 MB free and your own SLIP or PPP connection. No other software needed. Also runs on a Macintosh with Soft Windows installed.

****
This message was sent using E-Mail Blaster.

E-Mail Blaster is The World's Leading Bulk E-mail software.
With E-Mail Blaster you can advertise to over 100 million people for FREE!

Cost: We are giving away Email Blaster your only cost is $165.00 License fee.

THAT'S IT!!!

Our company is in the software business of developing cutting edge products, so we know if you have the opportunity to use our software FREE you will be our future customers. We know we need you to make our software business a true success!

(Please if our lists are incorrect put "remove" in the subject and just hit "REPLY" and you will not be bothered again. Please forgive our mistake).

>

You may want to look for 'Scotchbrite' which is a plastic
pad made by 3M. At one time the burgundy-red colored Scotchbrite
did not have any additional chemicals added to it. It is very
effecitve for cleaning printed circuit boards without embedding
steel fiber in the copper, or contaminating the copper with
chlorine (due to cleanser or bleach).

Many machine shops use it to clean metal and certain tools.
You may be able to find it at hardwre stores or machine supply
shops.

4409. Re: TS450 IF232 Protocol?

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-23 00:00:00 UTC
From: tenorman@i1.net
Message-ID: <5jk1np$f6g$1@news1.i1.net>
Source record: 94718
Cross-posted to: rec.radio.amateur.digital.misc,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc

The Kenwood TS450 uses the RS-232 serial protocol. The signaling is TTL logic level, that must be converted to +/-12 volt to interface to the more popular "PC" type signaling standard. This can be accomplished by purchasing and interfacing a MAX-232 chip (TTL - RS232 level converter), and a TTL inverter. Get a spec / interfacing sheet on the MAX 232 chip, it will explain how to build a simple converter board. After that, the rig communicates at 4800 baud, Hardware flow control, 8 data bits, 2 stop bits, and no parity (if my memory serves me). After that, the commands to be sent and received should be found in the supplimental guide that comes with the TS-450. If you don't have that book, email me, and I'll send them to ya. Good luck, 73, Mike - WQ0N

Forgot. If after cleaning, you'll put a moth ball or two in the box with the silver, you won't have to do it again. The Phenolthalien in the moth ball keeps the silver oxide-sulphide from forming. Put a piece of masking tape loosely over the mothball to keep it from rattling around.

Actually Marty, it sounds more like your ISP falls for every bogus news-
group that's created outside of the recognized and accepted procedure.
There was no Call For Discussion, nor was there a Call For Votes, and
there was no posting of any r.r.a.swap charter. Thus, it's bogus and
will eventually be cancelled.

(Are you sure it's not under the alt hierarchy?)

Hello all

I'm looking for a 10.7 MHz, 50-100 kHz bandwith ceramic filter that it
is near to impossible to find in Spain.

Anyone know for a source to take this small device? I know that muRata
and Panasonic manufactures them, but I don't believe they sell
unities...

Thanks in advance,

I've found this trick very useful. Look inside any radioshack device (2 meteramp Transeiver etc) if you find a part that matchs your needs call RSparts at 1-800-the-shack. Tell them you need that part! Inside the little 2 meter amp are 3 variablecap. I know 1 of them is a 10-50 pf unit. It'll set you back a cool $1.99....Good luck!

4420. Re: HW-8 Call to Experts.

You need the HW-8 Handbook, it has all kinds of mods and fixes for the HW-8. You can get one from Mike Bryce WB8VGE 2225 Mayflower NW, Massillon, OH 44647. The cost is $11 which includes shipping.

I have a HW-8 and it has the same problems as yours. The cure is to rewind the coils for those bands along with changing some cap values.

Good luck

Bob

If you have a 3 ft area fixed-shape loop, it ALWAYS has essentially
the same pattern and performance no matter HOW MANY turns of wire you
use as long as the total effective cross sectional surface are of the
conductors are the same.

> I never said it was dependent on the number if turns. I have
>repeated the literature's measured evidence that it is dependent upon
>the total length of the wire.

I'm not really sure what you are saying.

If you are increasing the diameter, then we are in agreement.

If you are maintaining the same loop diameter or area and increasing
wire length than I disagree.

This thread was dealing with small loop antennas. " I use 3/4 wl of
wire in mine" gives the impression you have a small loop with 3/4 wl
of wire. Do you have a small loop or a large loop?

From: donrm@sr.hp.com
Message-ID: <5jle14$92u@canyon.sr.hp.com>
Source record: 94736

Jack Giehl (jackg@one.net) wrote:
> Hi,
> I want to letter a panel with black lettering. I have used Datak lettering

Datak's phone is 815-874-2301 and FAX is 815-874-2896 and can probably tell you who distributes their dry transfer lettering. I checked Digikey and surprisingly, they don't carry it, but do other Datak products.

Make sure you get something that's still in date by looking for a four digit code in any corner - e.g., 8203 would mean the third work-week of 1982 -- and there's still some of this old material out there. Datak guarantees their stuff for five years, so anything earlier than 91XX is suspect and you may have difficulty getting it to transfer. Sometimes you can "pre-release" it by rubbing the letter onto the backing paper until it turns gray looking, then transfer it to your work.

Radio Shack used to carry a good house brand of dry transfer, but it's been gone out of their catalog for some time now...another thing you might do is check your art supply stores; they supply "A" size sheets of letters/numbers only with a large selection of colors/fonts. Expect to pay up to $10/sheet. Don't be afraid to try the individual characters; the sheets have datum lines to facilitate alignment and you can kern the characters anyway you want, even create shadow lettering by over-laying one color with another with a slight diagonal shift.

Happy Homebrewing

4428. Military Preamplificatore driver

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-23 00:00:00 UTC
From: dxhog@netsync.NET
Message-ID: <335E40EB.21CB@netsync.net>
Source record: 94737

At a hamfest recently I picked up one of those "GOT'S TO HAVE ITEM'S" that I need some information on. The small compact amplifier is solid state and seems to be in like new condition and is military. The amp measures 7"w x 2.50"t x 9"l, it has a very beefy heat sink and is built as you would expect any military piece to be manufactured. The outside of the case is marked Preamplificatore Driver, 2-55814//A, under that is this number 80063 assy A3026012. Upon pulling the cover, the circuit board has these numbers, 0-94170, MPA 39877, A3031540 in the upper right corner. In the lower left corner of the board is 80063ASSY A3026105. The unit has two drivers MRF466 at 28v and two finals MRF429 at 50v. Looking into the amp it appears that it was used as a pre driver for a very large amplifier. This unit with the driver's and final's that it has according to spec is capable of producing 300 watts. Pad on the input to the driver shows that about 2 to 5 watts will drive this and also looks to be about 75 ohm input. This unit is built to be rugged, as even the wire is teflon wire. From the construction of the unit it looks as if it will play from 1.8Mz to 30Mz, maybe as high as 50Mz. Thought that maybe someone out there could shed some light on this interesting unit. Doe's anyone have spec's, or a manual for this unit? I would like to put this into service with my QRP rig of 5 watts. Thanks for reading this and your time. 73 N2ODU/Dave.

Russ, one "trick" you might try is to put a DSP with pseudo COR output on the TS450 audio to simulate COR. JPS in Raleigh has such a mod for a little more than the price of their amateur product (high $300's) and you get DSP audio filtering as well.

You might also look at the Link Communications Controllers, They have TTL logic output on each radio port (one direction - to radio) to talk to the Kenwood directly without an interface.

Good luck, John

I have founded a new student amateur radio club at Cy-Fair
High School in Cypress, TX, and WE NEED YOUR HELP!! Before
the summer we will be getting our first batch of newly
licensed hams, but very few of them will have any money to
get a station on the air. If you can help with a monetary
or equipment donation of any kind, please point your browser to:

http://www.argohouston.com/pages/g/gewellss/

ALL DONATIONS ARE TAX-DEDUCTIBLE!!!

73's,

James A. Wells, KC5SIZ
President, Cy-Fair HS ARC
mailto:jwells@argohouston.com

Phil - I was surprised (and disappointed!) at all of the responses to
this request!

Where is Birkett and AJH in Rugby?

I would like ADDRESSES and PHONE NUMBERS for these two if they sell
such trimmers!!

Also - if you want a good long list of parts suppliers that may have
them, try this:

http://www.mnsinc.com/bry/hamfiles.htm

and click on PARTS

All the very best - Brian, AF4K / G3XLQ

Those wanting to build a QRP transmitter or transceiver may wish to have a look at sections of the Australian QRP Home Page and Novice Notes Online.

The following are just some of the topics covered:-

* VFO, VXO or crystal control in homebrew rigs?
* What is a reasonable output power for success on HF?
* CW, AM, DSB or SSB?
* Portable operating
* Ten secrets of QRP success
* Converting AM broadcast receivers to 160 metres (link)

Plus other material to interest the experimenter, the QRPer and the beginner to amateur radio. Simply click on the URL below to find out more.

73,

Peter Parker

4450. Looking for WB3JBG, KA5JVU, and KC5NG QSL cards

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-24 00:00:00 UTC
From: k5dh@qsl.net
Message-ID: <5jnl3v$m5i@sf18.dseg.ti.com>
Source record: 94619
Cross-posted to: rec.radio.swap,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.boatanchors

This is way off-topic, and I'm sorry for that, but here goes...

I'm looking for examples of my old QSL cards. Like a dummy, over the years I did not save examples of most of my cards. I want to put up a framed display of one of each of my cards in my hamshack, but I do not have them all. Actually, I can't even remember what some of them looked like.

I do NOT need these:
- WB3JBG card with tower/beam on front (my first QSL from 1977)
- KC5NG card with farm/barn/horses on front

I know one card was a promo from RCA, with a painting on the front side that depicted some sort of communications satellite, and my call would have been hand-written along the right-hand side of the front of the card. I only ever had 100 of these, so this one may be hard to locate.

I also used some temporary U-fill-in cards when I first moved from Delaware to Texas. These will also be very hard to find.

All of the other cards were bought from regular QSL vendors.

If you have one of my old cards that you'd be willing to part with, and the front side is in mint or near-mint condition, please email me and I'll make arrangements to get the card(s) from you.

Thanks very much and 73!

Note that is 5 to 10 nf "nanofarads" not pf "picofarads". That's 5,000 to
10,000 pf,
where common trimmers are 5 to 100pf. A 2-meter rig is unlikely to have a
5,000pf
trimmer. I misread this too the first time.

4453. Re: Would you like some extra money?? - projects

At first I couldn't see the connection between your note and
rec.radio.amateur.homebrew, but I guess I just wasn't thinking.

This isn't about money, its about getting more projects to work on!
Each of us has one or 2 projects that went sour, and is just sitting
on the shelf! Mine is a 2 meter receiver. It works sort of, but the
frontend is lousy, and it is impossible to tune due to a 1 turn pot
and a poor power regulation unit. Things improved somewhat when I
put it in a box, but it still isn't usable.

SO What's on your shelf??

Jeff's right (for once), rec.radio.amateur.swap is a bogus group. And any and all rec.ham-radio.* groups are bogus as well. They were replaced by the rec.radio.amateur.* groups in the grand renaming. And there is no rec.radio.amateur.packet group either. I've seen that as a bogus group on some ISP servers, but it, like the rec.radio.amateur.swap group, is the result of some sysop doing an illegitimate group creation. All Big Eight hierarchies have an established process for creating groups. None of these bogus groups have passed through that process. But if someone wants to do it legitimately, I'd vote for the creation of an amateur swap group, and for a packet group under the digital hierarchy too.

I've never seen compression trimmers as big as 10,000 pF, which is of course not to say they're not available. 10,000 pF has a reactance of about 0.1 ohms at 2 meters, so it's unlikely to be found in such equipment.

Check out my home page. I have some info on homebrew
attenuators.

Remember evaluate the power through each stage. NEVER
begin with the HIGHEST ATTENUATION at the output of your
amp. I.E. 100W AMP needs 1 Watt output. a 2 watt
20 DB atten. will absorb 99 watts. (Until it blew!)

Youll need probably a 3dB 50 watt, Another 3dB 25Watt,
and 10 dB 25 Watt. to get down to 2.5 watts output.

Above just an example.

This sounds like the samestuff I call Lettroset.
It's OK for very small projects... but when you
have to put several lines of the stuff on,
the second and third lines mess up the first.
Also.. when you have the letters on, be sure to
spray on some kind of clear layer to stop them from
being scratched or smudged.
Bob

6146A's, 6146B's, and 6146W's are still available. The characteristics
of each are slightly different and will probably require reneutralization,
assuming that the application you're using them in is a RF power amp.

4462. Looking for WB3JBG, KA5JVU, and KC5NG QSL cards

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-24 00:00:00 UTC
From: k5dh@qsl.net
Message-ID: <5joi4p$btc@sf18.dseg.ti.com>
Source record: 94631
Cross-posted to: rec.radio.swap,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.boatanchors

This is way off-topic, and I'm sorry for that, but here goes...

I'm looking for examples of my old QSL cards. Like a dummy, over the years I did not save examples of most of my cards. I want to put up a framed display of one of each of my cards in my hamshack, but I do not have them all. Actually, I can't even remember what some of them looked like.

I do NOT need these:
- WB3JBG card with tower/beam on front (my first QSL from 1977)
- KC5NG card that was a promo from RCA with satellite on front
- KC5NG card with farm/barn/horses on front

I also used some temporary U-fill-in cards when I first moved from Delaware to Texas. These will also be very hard to find.

All of the other cards were bought from regular QSL vendors.

If you have one of my old cards that you'd be willing to part with, and the front side is in mint or near-mint condition, please email me and I'll make arrangements to get the card(s) from you.

Thanks very much and 73!

"at least we are not using aluminum contacts"?
i, for one, do not understand the reference...
i do know that aluminum is not recommended for wiring due to
the potential of a fire hazard as the aluminum might ignite.
is the reference to aluminum contacts with regard to this???
would anyone care to elaborate on why aluminum is not used?

Given your requirements, I think you are at about the proper AC
voltage. The absolute AC requirements will (also) depend on the
transformer secondary resistance - how much drop under how much load.?.
Also will depend on the amount (value) of filter capacitor. More filter
capacitor will permit lower input voltage - to a point. If the
capacitor value is very high and the transformer secondary resistance is
low, beware of turn-on surge currents (check you diode surge ratings).
A slow turn-on circuit is sometimes needed.

4467. help on homebrew cavity filter

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-24 00:00:00 UTC
From: putra000@uwp.edu
Message-ID: <5jo9nn$3u4$1@news.inc.net>
Source record: 94636

Hi!

I am looking for help in setting up a homebrew 2meter repeater. the main problem I am having is one of isolation. Attempted to build a cavity filter, but at last hamfest I picked up a set of 2 for like $15! I have been able to tune them both as a 'reject' notch? filter for the receiver on the transmitter's frequency.
My problem: I have been unable to find any or VERY FEW references for helping me 1. tune the cavities, 2. build the cavities, and 3. Possibly use them as a duplexer.3. although it mentions that by adding capacitance or inductance you can modify the reject or pass, the handbook makes no mention of the proper values.
Looking in an older handbook, it mentions something about a 'hybrid ring' design, that uses specific lengths of coax to accomplish isolation. However, when looking at a more recent, 1996 handbook, there is NO mention of a hybrid ring design... Am I to assume that the measurements are from tip-to-tip of the two PL-259's, or is it only to the connector???
I amlooking for a place to go for help on the
theory, and getting it to work properly. If you know anything about this, or would be able to point me in the right direction for sources, please help!!

Thanks!
-John

Hi

I am about to make a test between a new germanium diode and a "old" crystaldetector. I have some galena, which I know could be used for the crystal detector, but how do I finish the detector: how shall I connect the 2 wires to the galena, and what sort of wires shall I use?

I want to make a diode-characteristic on the crystal detector. Does anyone have and idea how it would look like (so I have someting to "aim" for)

Hope YOU can help me :-)

Sincerely
Henrik Larsen

4472. Transformers and secondary voltages in DC power supplies

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-24 00:00:00 UTC
From: ik0rnt@quipo.IT
Message-ID: <1.5.4.32.19970424203629.008fc354@quipo.it>
Source record: 94641

I'm assembling a power supply to be used with my radio sets (typical output voltage: 13.8 volts). Since the transformer I've got had a too high secondary voltage (around 24 volts), it was worthwhile unwinding and removing some turns from the secondary winding to have a smaller voltage drop on the regulator, and hence a smaller power dissipation on it (at the moment I'm using a LM338; maybe I'll try a combination of a LM317 with a couple of MJ4502). Here comes te problem: what's the best value I can choose for the secondary voltage , assuming that I would like to be able to increase occasionally the DC output voltage up to 15 volts?
Of course, I've to take into account the voltage drop across the diodes of the bridge rectifier (0.7*2 volts=1.4 volts, if not little more; that depends on the voltage drop across the single diode) and the oscillations of the AC line voltage around the 220 volts mean value (I've realized that at home I've about 230 volts AC on the sockets, but I guess that in some other place of my city, which is Rome, there could be also 210 volts AC, and I would like the power supply to be usable everywhere). Is that really all?

At the moment the secondary voltage of the transformer is about 19 V AC when no load is connected to the DC output of the supply and about 18 volts AC when a load draws from the supply a current of 3-4 ampere. I'd like to reduce it further, to reduce the heating of the power stage, but I don't wanna risk to have to wind again the removed turns, whether something doesn't work.

Mostly, the question arises because I guess there could be something about DC power supplies I don't know yet. Is there anybody who can tell me, knowing more about this subject, how to make the best choice?

Excuse me for the lenght.

Jim, I think you misread the sizes. 5 nF is 5000 pF, or .005 uF. It's
hard to find full-size variable caps that big, let alone trimmers. I
suspect the original poster will have to redesign his transmitter.

"AC" electrolytic capacitors are not polarity sensitive like the normal electrolytic. The most common use is motor-start capacitors such as you may find in a rotor control box. As I recall, you can substitute two normal electrolytics back-to-back (at double the needed capacitance) for an "AC" electrolytic. There should be no reason you couldn't use an "AC" type in a normal DC circuit.

Go with an ARCO 466 or 467 and pad it with parallel silver micas. It will take some experimenting. The largest mica compression caps I have ever seen were 2700pf and had a 1/8" tuning shaft. Danny Stevig had them a few years ago.

The 6V6 was "reborn" as the 6AQ5. The 6L6 is too large to have been squeezed into a miniature form. The 6SK7 never had a mini version, but the same function (variable mu pentode) was performed by the 6BA6 (actually a mini 6SG7).

No it is not. At least not in the UK so don't generalise.
So long as the transmitted power is less than a regulation threshold
and he sticks to appropriate bands the pets never leave the house and
the transmitters are off when he is out.

Of course he needs an amateur license.

A better plan is to go any buy a device for the purpose using the
frequency band allocated.

To make one, don't use a 2m crystal. Use a crystal around 48 MHz
with a transistor oscillator and an output circuit tuned to the 3rd
harmonic. There is a circuit in the ARRL handbook in the Oscillators
section.

I have the "mortal remains" of a stripped-out Heathkit SB-102
sitting in my hamshack, taking up valuable space. It has been
heavily stripped, but there are a LOT of good parts left for
the Heath repairer/restorer.

THE FOLLOWING PARTS ARE ALREADY GONE:

Cabinet and front panel
panel meter (face was broken anyway)
LMO unit
main VFO dial (was shattered anyway)
all knobs
all tubes
PA tune/load caps
PA tank coil
both relays
driver tune caps
many of the tube sockets
power supply connector
RCA jacks
drive belts (weren't any good anyway)
some crystals
CW filter
random small parts

There are still LOTS of small parts, including the coil-pack boards,
some of the crystals (I don't recall which ones), etc.

I will give this away for free to someone who needs it. Maybe you
can trade me something that I need some day. First person to request
it, gets it. You pay the shipping charges via UPS.

I am in need of a hi power shorting bandswitch. Need on wafer with 9 positions. The amplifier gives a theoretical maximum of 1800 watts and covers 160 to 10m. Does anyone have one to sell or know where one can be bought ??
Any information would be highly appreciated.

Source record: 94566

I need to design/build/nick/steal :) a design for a high-stability phase-modulated oscillator (<5ppm) in the 400 mHz range. Physical size is important, and I expect to have to use a crystal oven. Questions:

1) Who in the U.S. makes crystal ovens, or temperature-compensated crystal assemblies?

2) Anyone MAKE high-stability oscillators like this in the U.S.?

3) Any suggestions?

4) Anyone out there a real cool competent digital RF design engineer who might be interested in undertaking this project?

Specs available upon request. Please reply via email, not to the newsgroup. Thanks & 73,

Steve!
have you ever tried to use multiple smaller value capacitors in
paralell?
In 2m and 6m power amplifiers I used 3-5x 100pF and varyed the value by
removing or increasing the amount of capacitors, I have also applied
this
for 80m QRP transmitter

>Thanks, Jack WB8BFS

This is a reprint of an earlier post:

I have a couple of methods that work pretty well, the simple one
first:

Design and print-out the label using a computer and a laser or inkjet
printer.
Using a do-it-yourself laminiating sheet, cover the label with clear
plastic. The material I use is called Cleer-Adheer, C-Line #65001,
from office supply stores.
To fasten the label to a panel use 3M transfer tape (the best way), or
3M Super 77 spray adhesive available from a hardware store.

A real neat way to do it is this:
Using a laser printer, print the label on "Toner Transfer System"
paper. This paper has a resin coating that is water soluble. I
believe Press and Peel Wet is the same thing. I bought this at a
local electronic parts store.
If you want color in your image, use the product Ibifoil from Ibico.
You can get this at office supply stores.
Next put several light coats of laquer over the printed image. Be
careful because the laquer solvent can dissolve the toner and cause it
to run.
After the laquer dries, soak the image in water. It will float off
just like a decal used for model airplanes.
Apply the decal and after it is fully dry, coat the panel with a light
coat of laquer.
Note: It may be necessary to apply a little musalige sp? glue to the
panel to make the decal stick. Using the glue dissolved from paper
shipping tape works well too.

They are in parallel, not push-pull, so dropping in a single one would
work fine.

>supplys.

Certain types of capacitors (electrolytic and tantalum, for example) are polarized. They expect one lead to always be positive relative to another. These caps are usually well marked + and/or -. Hooking them up the wrong way (or to an AC circuit where the polarity changes 60 times a second) can cause excessive current to flow. In fact, the capacitor can literally explode!

It should be fine to go the other way. An "AC" capacitor will work OK in a DC supply, though it will be very large (physically) and somewhat expensive relative to an electrolytic of the same value.

1nF = .001uF = 1000pF

Thus the original poster, philip de cadenet, is looking for something
with 5000pF and 10,000pF (ie .01uF) capacity.

While these do seem rather large for even 160Meter equipment, there is
no way you will find them in 2M equipment. Considering how large in
capacitance they are, I do believe that they will be hard to come by.
Which is precisely why this isn't a run of the mill question.

This used to work for me:

Set a small bottle cap on mom's electric stove.
Heat bottle cap until paint etc. burned off. (Stinks, oops)
Feed 60/40 rosin core solder into bottle cap until about half full.
Drop in chunk of galena and hold down if it floats too high.
Stick 1 end of a copper wire into solder puddle before it hardens.

You'll need some sort of moveable contact to touch various points on
the galena for the other connection. I've seen several references to
using re-bent safety pins, but I always got better signal levels with
a steel paper clip.

4507. Looking for: Fox-hunt receiver kit that I can modify for CAP use

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-25 00:00:00 UTC
From: perryrt@flinthills.com
Message-ID: <5jpcfr$aeu@news.flinthills.com>
Source record: 94650

OK, Folks, I need your help.

I'm involved with the local squadron of CAP (Civil Air Patrol). I'd really like to work some electronics into the education program we do with the cadets. Specifically, part of the SAR program uses DF equipment to search for aircraft ELT's (which go off in the event of a crash). I would really like to build a rudimentary DF receiver with the kids. Ideal parameters for this project should be:

1) a kit commercially available, that I can tune (or crystal control) to 2 freqs: 121.5 and 121.6 mHz

2) Battery powered (so we can take 'em into the field)

3) Kits not too complex to test or hideously expensive.

Suggestions? What I hope to do is start with "This is a soldering iron. Grab THIS end" and go from there. Anybody done anything similar?

Would an airband radio work with a decent S-meter and a good antenna?

Thanks alot for all your input!

Regards,

R. T. Perry

There is a old program that runs the modem in software, for both the
Radio Shack Color Computer and the IBM PCjr called TDD56. Although the
code may be useless, it also has a good doc file. Look on a Simtel site
or CD-ROM in the msdos section in the modem directory for TDD56.ZIP. Or
look for sites that specialize in software for the handicapped.

The protocol uses 45.5 baud 5 level "baudot"/Murray using the single FSK
tone pair of 1400/1800 hz, both ends use the same tone pair and the
carrier operates in a "vox" type mode where it's only send when
characters are being typed.

You might check to see if the TDD equipment can run with ASCII at
110 or 300 baud using the Bell 103 modem (full duplex FSK). Most
modems can support that, and I think some of the TDD stuff does too.

Just a cmos crystal oscilator will generate harmonics well into the
two meter range. To get some range make the collar a resonate loop on
the desired harmonic. A fm reciver will not detect it very well but I have
seen it done on baloons for the close in direction finder.

Interesting. If I remember correctly, a stock HW-100 has two 6146A's
running in push-pull. What sort of modifications do you have to
make to drop a single PL36 in there?

Tim.

>
>Would someone please explain the differance between the two types and
>the applications for use. Can the AC type be used for DC power
>supplys.
> Steve Carlisle VE7AHL

The AC types do not have their foils polarized and can accept voltage charge in either direction. They are physically bigger than the DC only versions of the same value.

NEVER NEVER NEVER hook to DC caps together in series backwards to make an AC cap. It doesn't work, an it will blow up in your face if given even half a chance.

Best wishes KD3SH

4515. Question about TDD for the deaf

Hello from KD3SH,
I would like to know if there is some type of terminal program or if it is even possible for my computer with a 14.4kb modem to communicate with a deaf persons TDD unit. I may be wrong, but I think they still use the baudot code and maybe some old tone groups. Please enlighten me on any possibilities. TNX and 73

You need a sweep generator that sweeps across your IF frequency thats
applied to the horiz and an output from your AGC that goes to the vert.

I've wondered about this in regard to my GT-550 running two 6LB6's
in parallel; I'd love to run just a single one. Even though it's
capable of running 550W input, I usually idle along at no more than
50W. No need to have both 6LB6's burning while running QRPo (or is
that QROp? ;)

4524. Really good regenerative receiver

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-26 00:00:00 UTC
From: Peter Parker <parkerp@pcug.org.au>
Message-ID: <3361dcc0.0@cheese.pcug.org.au>
Source record: 94590

Further to the discussion re SW receivers, I've just put together the best regenerative receiver I've ever built (valve or transistor). It appeared in Communications Quarterly Fall 1995 and Radio Communication April 1997 (built by N1TEV).

It uses two FETS (not critical) and an IC audio amplifier. The chip specified was weird and required a split supply rail so I substituted an LM386. Worked first time - the only thing was that I needed to wind a few more turns than specified on the regeneration tickler coil as I was using a smaller than specified regeneration variable capacitor. My unit covers 3-10 MHz and is in a large metal box (front panel nearly the size of a TS520s!). Three vernier drives grace the front panel, and it really looks like a homebrew transceiver, though when you open it up there's almost nothing in it - just 2 transistors, a coil and an IC. Audio quality on AM is first-class on the SW bcast stns.

73,

Date: 1997-04-26 00:00:00 UTC
From: LA8AK <la8ak@online.no>
Message-ID: <3361FC41.ED6@online.no>
Source record: 94594

It really depends on the actual set - what is possible - dependent on the size of the holders. I run 5894 (QQE06/40) with 190W RF out on 2m, YL1070 is ssb tube, and YL1060 either has 60-70w anode dissipation and they are as such better than 5894/QQE06/40. The problem is that the socket (same as for 832A and 829B) - it might not be possible. Perhaps one valve?
I believe it is not difficult to locate 6146B, I have some for my FT902, and I know about several good sources, there are many sources, I feel persons often wish to have replies like using 6BQ5 for 6146.....

Markus,

I believe there may be some legal problems here. In order to do as you decribed, your pet dog or cat must be licenced to operate in the 2m band. Not to worry, for 2m all the dog or cat needs is a technician "no code" licence. Otherwise I would suggest operating in the CB band, where no licence is required. Good luck an' keep the pedal to the metal, good buddy!

: Just stick two high-speed rectifier diodes, capable of conducting
: forward several amperes of current, back to back, and you are
: protected. All voltages exceeding 700mw will be clipped thusly.

As has been mentioned, back to back diodes are an invitation to
intermod. How much ESD protection is needed? My solution would be a
miniature neon bulb across the rx feedline. A neon bulb will conduct at
around 70 volts or so (can't remember exactly). Don't use the type of
neon bulb with the built-in resistor, just a plain neon bulb will do.
This will also work on a feedline used for tx if the bulb is attached
at a low impedance point and both SWR and power out are low enough
(for 50 ohm line, somewhere a few watts below 50 watts out--calculate it).

Aluminum oxidizes almost immediately when exposed to air. The oxide forms a very thin layer and is very hard. (Aluminum oxide, a ceramic material, is commonly used for sandpaper.) It's also an excellent insulator. (It's used as a substrate material for circuitry operating at frequencies well into the microwave range.) So you have contacts with an insulated coating. If you apply enough pressure to break the coating, the broken pieces imbed themselves into the soft aluminum underneath. When the contact is broken again, more oxide forms and is again broken the next time the contacts mate. In a short period, the contacts look like a battleground with jagged chunks of insulating material jammed into the soft aluminum, with very little exposed unoxidized aluminum left to make contact. This will also happen in the presence of vibration. The combination of this effect and the difficulty of permanently clamping such a soft material makes it difficult to make a reliable connection with aluminum. One thing that has to be done is to keep oxygen away from the connection. For house wiring, this is done by covering it with a greasy compound like NoAlox.

Tin contacts have the same problem, although it may not be as severe. But in my experience, tin contacts will just about always cause trouble sooner or later.

When aluminum is exposed to air it immediately forms a thin layer of
aluminum oxide which is non-conductive. You can see this effect
yourself with an ohm meter. Gently touch the two probes to a piece of
aluminum and it will show an open circuit. Press down hard enough to
puncture the oxide layer and you will have continuity.

Correct. Most MOSFET devices have back-to-back zener diodes
connected from the gate(s) to the source.

I've just finished testing a unity gain antenna buffer that has
an IP3 of +35dBm. It uses a lowly J309/310 and a couple of bipolar de-
vices. I had previously considered using a dual-gate GaAsFET, but the
discussions here and elsewhere had led me to believe that I should use
something that's safer ESD-wise.

I gotta go.

My God!!! I cannot believe I am reading crap like this in a "technical"
area!!!!

To read a MSTR II freq, KEY THE DAMN TX and read it with a freq counter..
to set the RX to freq, determine what the IF is (11.2 or 9.4 Mhz) and is
the LO low side or high side injection? (typically LOW side)..
then couple the freq counter to the MIXER board and read the ACTUAL LO
freq (I can do the same by attaching a service monitor ANT to the RX
input of the GE and read the LO there)

GEesssh people, it aint that hard!!

I'm not going to get into this any more than this:

the use of back-to-back electrolytic capacitors to form a
non-polarized capacitor is a common practice. Amost any commercial
RFI filter rated for AC service (with a total capacitance over 1 uf)
is constructed using back-to-back polarized capacitors. And the
practice of using large electrolytic capacitors back to back with
reverse-polarity protecting diodes across them as a relacement for
non-polarized capacitors is a successful practice that has been around
for many years.

O.K. to the replys about using diodes,

if you need 100 mfd ac cap and make one using two 200 mfd dc caps back to back with diodes it may work somewhat well on a sine wave with a well behaved load. If on a complex wave, you charge down one of the caps until the diode conducts, you now have a 200 mfd coupling cap instead of the 100 you were shooting for. This may make a differance.

Just do like a good engineer and don't replace an ac cap with a pair of dc caps. Also the dc caps may not handle the ripple current.

The lesson, unless your project is supposed to bang and smoke, don't do the two dc's equal one ac.

Steve Carlisle (carlisle@capescott.net) wrote:
: Would someone please explain the differance between the two types and
: the applications for use.

The normal power supply electrolytic is polarized, due to its dielectric film. Used reversed polarized, they break down rapidly and short.

Motor-Start and Motor-Run capacitors are designed to work with AC currents. As industrial-strength components, their voltage ratings usually have a safety factor of four or five times, meaning they won't usually fail even if voltage ratings are constantly exceeded.

The metal-can type (liquid-filled) has an oil dielectric and is made to work under constant-duty service with AC. The plastic-bodied type is supposed to be used in intermittent-duty service on AC, and not in constant-duty service with either AC or DC.

: Can the AC type be used for DC power
: supplys.

The oil-filled metal units are preferred by audio-buffs for tube supplies. They were used for filter service in many heavy-duty power supplies. Highly recommended. Because they are fully sealed, they last forever (so I'm told). Lots available in surplus stores. I've seen several old QST projects using oil-filled caps.

I am presently using a pair of the plastic-bodied ones as filter caps in a power supply (400VDC @ 100mA). No problems at all, although there are conflicting opinions on whether this is proper. They filter just great.

Buy the metal cans to be absolutely certain.

Wondering if you are using the QST article "Solid-Tubes- a New Life for Old Designs" by Sartori, April 77---?

In the article, he explains how you can make solid state tubes for most any application- but its not simple, so I suppose that you might do well in such a cottage industry, now that boatanchors are in vogue.

However, those attempting to put such tubes into a relatively high performance design may be dissappointed. The limitations on collector/drain current caused by dropping down from 100v or so, severely limits the IMD performance of such homemade devices.

That was certainly the case with the R4-C.

Have fun! Rob

ps. there may be some interest in a solid state tube replacement for the vox relay driver in the T4X-ABC, as the tube is very hard to find, I think its the 6EV7.

> (snip snip snip)

It might help if you let us in on what exactly you are looking for. SSB? CW? FM? Do you want to do local stuff? Drive microwave transverters? Packet? Satellites? Why do you want to do this?

If you want cheap SSB/CW, simple VXO-controlled rigs are cheap, easy to build and generally hard to beat. If you want FM, there used to be crystal controlled stuff in the ARRL and RSGB Handbooks, among other places. But with the passage of time they may be hard to reproduce now. The economics don't work, either, when you look at the price of new entry-level gear - don't forget to include the price of crystals!

I certainly don't mean to discourage you, but let's be realistic about this. The absence of plans may be telling you something.

I've never seen a 100 uF AC cap. Where would such a beastie be used?

All I've seen for AC caps are phase shift caps for motors and caps used in audio applications (coupling and crossover networks), and these all have been relatively small values, all less than 10 uF.

For motor apps the currents can be large so it is wise to heed the advise to refrain from the back to back caps, but for low power circuits the back to back arrangement works fine. Just don't use tantalum caps!! They are very sensitive to reverse voltages and will let you know in no uncertain terms!

By the way, many aluminum electrolytics have -20 +80 percent values, so watch out in those critical circuits.

Also, the diodes have a dual function. Besides protecting against the cycle
by cycle reverse current in the caps they protect against reverse polarity in
the asymetrical waveform cases where DC balance slowly changes.

This is also why Tin-Tec radios have so many intermittant problems. The stupid solder (lead/tin) coated Molex pins used in the interconnect harness become resistive. Quality equipment uses gold flashed pins.

I'm sorry to say, that won't cut it when you're using a MOSFET
in your front end. In fact, the break-over is so much lower than 70
volts that I laughed when I read this. This kind of trick reminds me
of the old vacuum tube days. Also, how much current can an ionizing
neon tube shunt? A diode will switch on and shunt AMPERES at just 700mw
while a neon won't conduct before 60 volts, and will only shunt
a few milliamperes before it dies. An MOV (Metal Oxide Varistor) would
be a better bet to shunt 60 volts, either that or a sidactor.....sq

(afraid of intermod? That's easy, two series strung diodes in parallel
back to back. This will then shunt at 1.4 volts, WELL below the damage
threshold of the gate on the device, yet well above the typical RF
voltage levels coming in. I think I posted that solution as well.....)

17 volts is still MORE than enough to blow out a MOSFET. You
want to keep it somewhere below 3 volts or so, and it needs to have
very fast turn-on, thus a diode or zener is optimum choice........sq

(mov's tend to turn on over milliseconds, not picoseconds like diodes.)

That's not exactly true. I can buy zeners in the range of 1.2
volts all the way up to 1000 volts. if you stuff two 1.2 volt zeners
in series so that one is forward while the other is reverse biased, it
will clamp at 1.9 volts. That would be excellent for the task.......sq

(you must be used to seeing 5.1 and 12.1 volt zeners only.............)

You are wrong. Think about why aluminum wiring is generally forbidden for use in home construction; Now think about metal oxide semiconductor gates. 70 volts of static EMF across a feedline is nothing, particularly when you consider that a mosfet's gate is already tied to ground via a resistor or a transformer winding. (And as has been pointed out by others, most mosfets are diode clamped anyway--yuck).

: Also, how much current can an ionizing neon tube shunt? A diode will
: switch on and shunt AMPERES at just 700mw while a neon won't conduct
^^^^^
Huh? Do you mean 700 mV?

: before 60 volts, and will only shunt a few milliamperes before it dies.

Wrong again. ESD is *very* low current. Why do you think your wrist strap at an ESD work station has over 1 Meg Ohms of resistance to ground? It works and it keeps you from being electrocuted in case you touch the mains. Apply Ohms law. ESD currents are on the order of microamps at best, not even milliamps. On a high performance front-end, even a Meg ohm resistor across the feed line is far preferable to diode mixers.

If ESD currents were of the order which you claim, then we would all be dead. Check out the biological effects of electricity. Current is a complete non-issue as far as ESD is concerned.

Face facts, for a high-performance rx, avoid hanging mixers across a feed line. A neon bulb is preferable by far. In fact, I wouldn't even worry about ESD if the gate of the device I wish to protect has a reasonable path to ground--which means most any normal design.

> Wrong again. ESD is *very* low current. Why do you think your wrist
> strap at an ESD work station has over 1 Meg Ohms of resistance to
> ground?

The processes that place large electrostatic voltages on objects tend to be very low current, so a large bleeder resistance can drain off the charge as fast as it is supplied, preventing a discharge. However, in an actual electrostatic discharge event the currents are quite high, typically several amps. The duration is short, usually well under a microsecond, too short for serious biological effects, but it can easily damage a semiconductor device.

A system "protected" by a bleeder isn't protected against a discharge due to contact with an unprotected external object (cable, person). The charge on a single raindrop may be sufficient to cause damage in extreme cases.

This is a hard problem to solve. Zeners and MOVs have been mentioned, but they tend to have too much capacitance to be useful even at video frequencies. Ne bulbs, and their bigger brothers designed for lightning protection, have low capacitance but their clamp voltage is generally too high (a multilayer approach with a gas discharge tube out front, followed by a lower voltage device, can be very effective). High conductance, low capacitance diodes (1N914B) are fairly effective, but may produce mixing products. Reverse biasing the diodes with batteries or a quiet power supply helps.

There's a fairly new IC protection technology I haven't tried yet that may be a bit better than diodes: check out <http://www.semi.harris.com/datasheets/tvs/sp720/>. These things may still produce mixing products, but I suspect they make less than diodes. The Harris site also has a lot of useful information on ESD protection in general (no connection, just a satisfied customer).

A few comments here:

First, remember that noise figure and dynamic range are system properties, not component properties. Doing well on these specs is not so much a matter of magic components as it is a matter of getting the details right.

The useful frequency range of active antennas is from longwave to shortwave. Especially at the lower part of this range, neither GaAs MESFETs nor Si MOSFETS will yield optimum noise performance due to "1/f" noise (also known as "flicker" or "excess" noise). In this frequency range, JFETs and bipolars dominate low noise design.

Note that there is nothing magic in gallium arsenide that automatically reduces noise. Thermal noise voltage in a GaAs FET is about the same as in an Si FET with the same transconductance. What GaAs has is a higher electron mobility, so the GaAs FET can be smaller for a given transconductance. This reduces the capacitances and transit times. This is much more of an issue at microwave frequencies. A nice cheap J308 has 10-20 times the capacitance of an MRF966, but it has about the same transconductance. At HF it's probably quieter, and at LF it almost certainly is. GaAs FET sheets don't have noise specs at these frequencies, but the Motorola sheet shows minimum noise figure for their MRF966 test circuit at 500 MHz.

Also, don't count out bipolars for untuned loops. Thermal noise voltage is very low in bipolars relative to FETs, and shot noise is often not a problem at low to moderate impedances. The dynamic range rap against bipolars is misleading: a bipolar with a well chosen emitter resistor can often beat a FET.

There's a good section on low noise design in Horowitz and Hill's "The Art of Electronics", primarily applicable to the audio/video frequency range (but that's what we're in: "real" RF these days is mostly microwaves :-).

:complete non-issue as far as ESD is concerned.
:
:Face facts, for a high-performance rx, avoid hanging mixers across a
:feed line. A neon bulb is preferable by far. In fact, I wouldn't even
:worry about ESD if the gate of the device I wish to protect has a
:reasonable path to ground--which means most any normal design.
:
:Thomas (ars KI4N)
:tgm@netcom.com
:[use the word "rabbit" in the subject line of e-mail directed to me]

I didn't know the discussion was about ESD. I thought we were talking
about high voltage induced on the rcvr input via nearby transmitters, since
the early posts talked about IMD. With transmitters, you could have
considerable current into the rcvr.

Also, I thought that commercial gas discharge tubes were available for
transient suppression? Don't they contain hydrogen, a very fast conductor?

Also, usually the limitation on speed of gas discharge tubes is not the
initial turn-on, but instead the recovery time. Thats why thyratrons are
so slow.

The ruggedized version is the 6146W. This tube is still available
especially if you have access to a military/surplus source.

it is fairly easy to design transistor equivalents for certain
application of a valve, but worse to use this 'valve' in another
application. Oscillator valves being quite difficult to redesign, while
dc amplifiers are easy. 6EV7 shouldn't be too difficult for the TR4

There will be a proliferation of very low power signals in very tight
beams. They will presumeably be quite frequency stable (the key to high
data rates) making them easy to filter out. Have you ever noticed the
high power 10GHz microwave links the telecoms have used for years?
In city hams may face a greater challenge but these problems should be
solvable if we don't run off all the technical people in this hobby.
I don't think it is nearly the problem that we were presented in
Central America with the confiscation of the entire UHF spectrum You
can't adapt to new challenges when you have no access at all.

What about MOV varistors (surge suppressors)? I've seen them in 250A
sizes as small as 17 volts. If you've got 17 volts of RF on your
preamplifier, it sort of begs the question of why you've got a
broadband preamp of any sort in your front end. The same would go for
higher-voltage zeners...

One of the really cool things about the J310 is that they're only 34
cents each from Motorola. It may be cheap, but there seems to be a
sentiment among some radio experimenters that it's a "golden" part.

Working on a baseband sub-processor for killer homebrew rig and need some help: I know of the following commonly used signalling formats - are there others? Especially looking for formats that are public or at least published somewhere. The following list contains lots of (R), TM, etc. - ownership as applicable where not noted:

Continuous Tone Coded Squelch System (CTCSS)
Digital Coded Squelch (DCS)
Single Frequency, Two-tone Sequential like
Motorola Modified General Encoding Code Plan
Motorola General Encoding Code Plan
Motorola Code Type Assignment Method
Metro-Page 10 and 100 Code Plan
Motorola Sub-Audible Code Plan
Modax / Moden / Alert Center Code Plan
GE Code Plan
Quick Call (Code Type Y)
Decimal Digital (5/6) Paging
HF AIRINC SELCAL 2+2 Paging (aviation)
DTMF Code Squelch / ANI
DTMF Paging (the nnn*mmm kind mostly amateurs use)
DTMF Messaging (the Kenwood kind; anybody know if it's on-line anywhere?)
ASCII ANI
Trunked - Motorola
Trunked - Logical Trunked Radio (LTR-E J Johnson)
Trunked - EDACS (GE)
Trunked - SmarTrunk
Single-frequency Inversion
Split-band Frequency Inversion
CODEC means, like Moto ASTRO, SecureNet, GE SecureGuard, etc.
AX.25 Packet (HF, VHF, 9600 baud)
RTTY (all modes, shifts, etc.)
CW (A1 and A2)
SSTV (all modes)
Digital Selective Calling (maritime)
Emergency Alert System (new) and EBS (old)
IMTS (is this still on the air anywhere?)
Station control tones like
Non-Simulcast Key Command Function Tones
Simulcast Key Command Function Tones
Station Group Disable (Knock-down) Tones
The International Radiotelegraph Alarm (maritime)

The International Radiotelephone Alarm (maritime)
Class A/B EPIRB Sweep Alarm

Thanks!

73 de Rob wm8s@pobox.com

I am looking for an inexpensive 6 Meter transmitter (or transceiver).
It does not have to be high power - only need about 1 watt (voice, not CW)
I already have a 6 Meter receiver.
I don't want to spend more than $150.
Please email me directly if you know where I should look for one.

Thanks,
John N7MTB

>: before 60 volts, and will only shunt a few milliamperes before it dies.
>
>Wrong again. ESD is *very* low current.

Let's take an example. Long time ago I used an ESD gun for testing some devices. The ESD gun consisted of an EHT generator (several kV) charging a capacitor (nanofarads) and the test charge was launched through a test tip to the device under test. If we assume for simplicity U = 1 kV and C = 1 nF and since C is defined as charge (Q) per voltage (U):

$$C = \frac{Q}{U} \Rightarrow Q = CU$$

$$\Rightarrow Q = 1\ nF * 1\ kV = 1uC = 1\ uAs.$$

However, when you connected the charged capacitor to the device under test, the discharge current is only limited by the series impedance of the circuitry between the capacitor poles. The series resistance in typical ESD cases into metallic objects is minimal, but the inductance is important. I have used a ballpark value of 1 nH/mm for PC tracks and bypass capacitors leads and it should also apply to this case. If the total conductor length between the capacitor poles is 100 mm, the inductance is 100 nH. Calculating the resonance frequency with the 1 nF capacitor will give about 16 MHz and the inductive reactance is 10 ohms. The half cycle time is about 30 ns, in this time the whole 1 uAs charge has flown through, giving an average current of 32 A will flow.

This is a simplified calculation, which is only intended to show the order of magnitude of the current and it should not be used for design calculations.

>Why do you think your wrist
>strap at an ESD work station has over 1 Meg Ohms of resistance to
>ground? It works and it keeps you from being electrocuted in case you
>touch the mains. Apply Ohms law. ESD currents are on the order of
>microamps at best, not even milliamps.

The current starts out as 1 mA from a capacitor charged to 1 kV. At
that current the 1 uAs charge is discharged in 1 ms, but compare this
with the 30 ns time obtained previously. Or calculate the time
constant for 1 nF and 1 Mohm or 1 ms in which time the capacitor
voltage has dropped from 1000 V to 370 V (37 %).

>On a high performance front-end,
>even a Meg ohm resistor across the feed line is far preferable to diode
>mixers.

But only to bleed of the slow build up of the charge, not the sudden
discharge when you touch the antenna. An even better solution to bleed
of the slow build up of charge is to use transformer coupling in the
input, when the antenna is DC-connected to ground through the primary
winding. Unfortunately it does not help much for sudden discharges,
since the dV/dt in the primary will also be transformed to the
secondary and into the amplifier.

>
>If ESD currents were of the order which you claim, then we would all
>be dead. Check out the biological effects of electricity. Current is a
>complete non-issue as far as ESD is concerned.

When the same charge is discharged through the skin, the inductance is
usually much larger and the skin resistance is in kilo-ohms and the
series impedance is many kilo-ohms limiting the current.

>
>Face facts, for a high-performance rx, avoid hanging mixers across a
>feed line. A neon bulb is preferable by far. In fact, I wouldn't even
>worry about ESD if the gate of the device I wish to protect has a
>reasonable path to ground--which means most any normal design.

You forgot the inductive reactance of that path to ground.

:A few comments here:
:

:Note that there is nothing magic in gallium arsenide that automatically
:reduces noise. Thermal noise voltage in a GaAs FET is about the same as in
:an Si FET with the same transconductance. What GaAs has is a higher
:electron mobility, so the GaAs FET can be smaller for a given
:transconductance. This reduces the capacitances and transit times. This is
:much more of an issue at microwave frequencies. A nice cheap J308 has
:10-20 times the capacitance of an MRF966, but it has about the same
:transconductance. At HF it's probably quieter, and at LF it almost
:certainly is. GaAs FET sheets don't have noise specs at these frequencies,
:but the Motorola sheet shows minimum noise figure for their MRF966 test
:circuit at 500 MHz.

True. Keep the GASFets to VHF and above.
:
:Also, don't count out bipolars for untuned loops. Thermal noise voltage is
:very low in bipolars relative to FETs, and shot noise is often not a
:problem at low to moderate impedances. The dynamic range rap against
:bipolars is misleading: a bipolar with a well chosen emitter resistor can
:often beat a FET.

For amps not needing isolation between input and output, or where input impedence as a function of ouput termination is not a problem, those popular Norton feedback circuits would probably work well.

Otherwise, I'd try using a FET like J318 with the source-gate feedback as described in Haywards "RF Design" book and used in the Carver "High Performance IF..." QST article.

Rob.

Tim,
Although I'm no expert on the subject, I'm informed that gel cells are
very sensitive to overvoltage and will easily gas if so charged. This
will serve to reduce their life. The info with my cells warn me not to
charge at more than 2.35 volts at 68 degrees f, (14.1 v). Check with
your manufacturer to confirm the best charging proceedure.

Surplus Electronic Components, Equipment, and Computer Hardware For Sale

http://www.concentric.net/~vstemen/surplus-top.html

Contact information:
Phone: (405) 947-8979
email: clstemen@usa.net

Please check our web page periodically for new stuff. We are still
figuring out what all we have.

We are located in Oklahoma City. If you are not in this area then
shipping costs will be added to your purchase, or on larger items, we
can negotiate arrangements for us to deliver.

==========
8530 hdlc/sdlc ISA cards
==========
Description: Serial cards. Great for HAM packet radio or
any other serial communications under Linux.
Condition: New
Price: $35 each OBO
Quantity available: 200

==========
96 pin male DIN connectors
==========
Description: 90 Degree right angel PCB mount
Same type of connector used on euro-cards
and VME cards.
Brand: Berg Electronics
Part Number: 75882-396 441036
Condition: New
Price: $2.00 ea.
Quantity available: 800

==========
Assorted capacitors
==========
Description: All sorts of big electrolytic capacitors, high and

low voltage.
Condition: Used / Pulls
Price: Cheap. All different prices. Too many to document :-)
Quantity available: Hundreds

============================
Assorted components
============================
Description: Resistors, capacitors, diodes, transistors, etc.
Condition: New
Price: Cheap. All different prices. Too many to document :-)
Less than half of Digi-key's prices.
Quantity available: Hundreds of thousands

============================
19 inch racks
============================
Description: 6' high 24" deep. All identical and will bolt
together in a column. Most have doors. These
are nice racks suitable for a TV or radio station
or computer room.
Color: Black with aluminum trim across the top front.
Condition: Used but in excellent condition.
Price: $75 each OBO.
Quantity available: 28

============================
2.2 kw xenon bulbs
============================
Brand: Optical Radiation Corporation
Part Number: 33030-1100461-2 rev L
Condition: New
Price: Make offer
Quantity available: 15

Hi Tom,

The two outputs are 90 degrees out of phase w/ each other- this is typical of hybrid combiners/splitters. If you anticipate using a pair of these to first split pwr to a pair of amps and then recombine- you connect them so that amp a is retarded 90 degrees at input, and amp B retarded at output (or vice versa) so they are in phase after recombining.

Jim ...

It is the king of mobile antennae. I have been using one for a few months and I have a better signal mobile than I do at my condo with attic antennae. GLA systems, PO Box 425, Caddo Mills, Tx 75135 Phone # 1-800-588-2841 to order 903-527-4163 for questions.

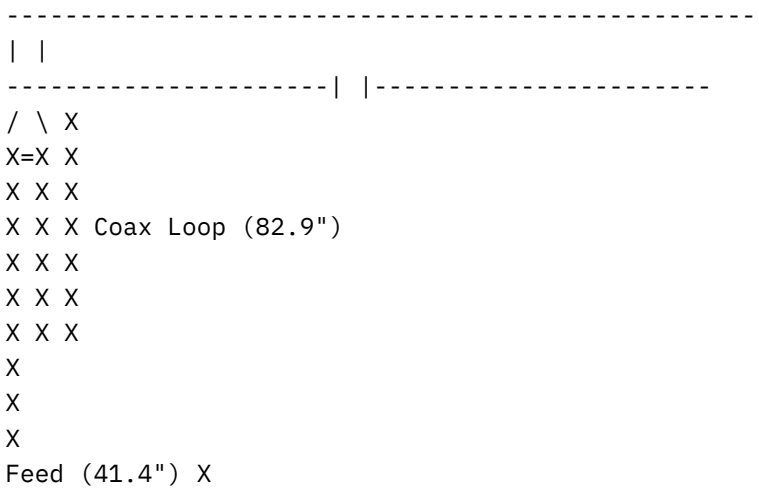
4628. Antenna Help Needed

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-29 00:00:00 UTC
From: Brian <brianb@hughes.net>
Message-ID: <3366ABBE.5CD4@hughes.net>
Source record: 94501

I am trying to build a directional antenna that I can use with my scanner (receive only) to locate signals.
I have experimented with a number of designs but I am making slow progress since I know only a little about rf stuff. Any help would be appreciated.

The design that sort of works is as follows:

I took a piece of PVC approx. 1/4 wavelength long and wrapped a 1/2 wavelength piece of wire around the perimeter so the antenna ended up being approx. 1" tall and quite wide. The two ends of the antenna loop are hooked to each end of the center conductor of a 1/2 wavelength loop of RG59 coax. The lead in is a 1/4 wavelength long RG59 coax with the center wire tied to one side of the antenna and the shield tied to the shield of the loop of coax.



The antenna picks up signals quite well but the directional aspect of it needs improving. It would also be nice to eliminate the loop of coax and reduce the size of the antenna.

Here are the calculations I used:

Wavelength=300,000,000/47,000,000=6.382979 Meters (251.3 inches)

RG59 Wavelength=.66*6.382979=4.212766 Meters (165.9 inches)

As you can tell I am a beginner at this rf stuff (digital background) so any help would be appreciated.

Please respond via E-Mail.

Thanks,
brianb@hughes.net

>see these systems deployed rapidly as soon as 1998 to provide non-commercial
>and commercial services on these frequencies.
I haven't read that R&O yet but I did read the December one which originally allowed a maximum of 4 Watts ERP on the 5.8 GHz U-NII band, with unlimited *receiver* antenna gain and 1 Watt maximum transmitter power. It sounds as if they just decided that the asymmetry wasn't worth the bother, so you can use one highly-directional antenna for both transmitter and receiver. Makes sense to me.

In typical U-NII service, there will be cellular-style base stations with directional antennas pointing at them. Spectral density is VERY limited: The 1W TPO is actually 50 mW/MHz, so if you're not at least 20 MHz wide, you have to derate power. This tends to reduce interference potential dramatically, especially compared with ham-style narrowband emission.

The U-NII band is one of the best things the FCC has done in years, a real gift to the public, finally a chance to do *something* without being beholden to the "Bell" interests. The h-r-online article is so utterly parochial that it seems like a discussion of World War II that begins with the headline "Church artifacts burned in fire". By opening this band up with VERY loose rules, save for power density, the FCC finally allows the public to have useful access to valuable spectrum! We who have been hams are the most likely ones to know how to use this, but it's certainly not in the antiquarian manner to which the A.R.S. has become accustomed.

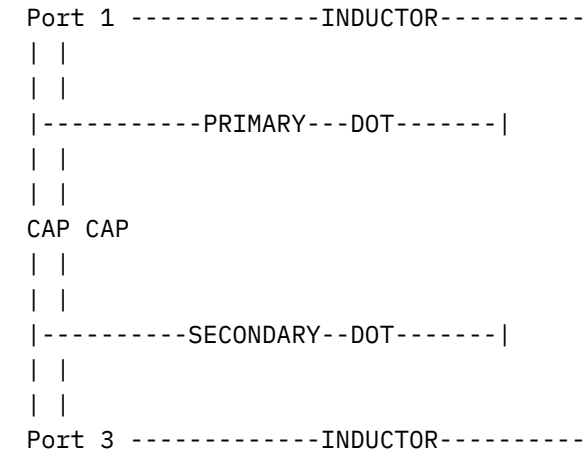
>works.
>Tom Faloon

Perhaps this will be helpful. Anytime I need a quadrature hybrid
(what you are calling a 90 degree RF power splitter), instead of
buying one from Mini-Circuits, I build my own as follows:



The capacitors and inductors have a resistance of 100 ohms at
the center frequency (assuming Zo = 50 ohms). The primary and
secondary are windings of a 1:1 transformer such as the Mini
Circuits T1-1 or T1-6. If you wind your own transformer, you
have the option of using a low permeability high Q core and
combining the inductors with the transformer; ie, the inductances
would be magnetizing inductances.

This design is a lumped element chunk of transmission line. Basically,
signals from port 1 to port 3 or port 2 to port 4 get a phase advance
because they go through capacitors. Similarly, there is a phase
lag from 1 to 2 and 3 to 4 because of the path through the inductors.
You can cascade several sections of this to get more bandwidth
but I've never seen a good paper telling how to do it. You would
have to deduce it from papers on transmission line types of
directional couplers.

To use this, call port 1 the sum port, port 3 the phase lead port, and port 2 the phase lad port. Port 4 gets a 50 ohm resistor to ground that absorbs reflections from ports 2 and 3.

Hope that took some of the mystery out. For more information read Barney Oliver's paper in Proc. IRE about 1954.

It gives me no end of comfort to know that at last someone has come up

with an irrefutable law in Electricity. You cand to **this,** and
some one has proven there is no **that,** and now we have an anchor
for the soul of electricity that is sure and certain.

Or it is until someone else proves different.

I believe one of the first things we were taught in college physics was NEVER TRY TO PROVE A NEGATIVE. All you can prove is you don't know how to do it.

Ciao baby.

The ARRL Handbook 1995/6/7, chapter 17, has a brief writeup on three types of combiner/splitter circuits, including the 90 degree type, and also several references.

Why would you want to do that? The price of these tubes is at a
very low level, so what is the point of going to all that effort
to replace them, not to mention the fact that the radio would no
longer be original if you put solid state tube replacements in
it. This type of modification is ok as a last resort for
unavailable types, but at the moment, these tubes are so common
that McDonald's may start packing them in Happy Meals!

Well, for one - I'm hoping he succeeds - it would be a small step from his "working" 12BE6 to a 1L6 ---- and it's makes a _whole_ bunch more sense to experiment with a simple and inexpensive AA5 chassis and tubes than risking - say an H500....

Besides - like many things in life - the trip is sometimes more rewarding than the destination...

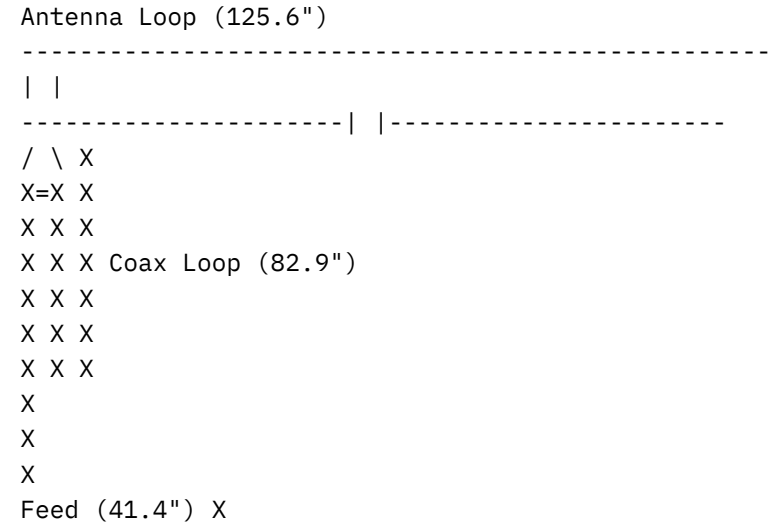
4642. Antenna Help Needed

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-04-30 00:00:00 UTC
From: Brian <brianb@hughes.net>
Message-ID: <3367E0CA.54D1@hughes.net>
Source record: 94416

I am trying to build a directional antenna that I can use with my scanner (receive only) to locate signals.
I have experimented with a number of designs but I am making slow progress since I know only a little about rf stuff. Any help would be appreciated.

The design that sort of works is as follows:

I took a piece of PVC approx. 1/4 wavelength long and wrapped a 1/2 wavelength piece of wire around the perimeter so the antenna ended up being approx. 1" tall and quite wide. The two ends of the antenna loop are hooked to each end of the center conductor of a 1/2 wavelength loop of RG59 coax. The lead in is a 1/4 wavelength long RG59 coax with the center wire tied to one side of the antenna and the shield tied to the shield of the loop of coax.



The antenna picks up signals quite well but the directional aspect of it needs improving. It would also be nice to eliminate the loop of coax and reduce the size of the antenna.

Here are the calculations I used:

Wavelength=300,000,000/47,000,000=6.382979 Meters (251.3 inches)

RG59 Wavelength=.66*6.382979=4.212766 Meters (165.9 inches)

As you can tell I am a beginner at this rf stuff (digital background) so any help would be appreciated.

Thanks,
brianb@hughes.net

>
> You are wrong. Think about why aluminum wiring is generally forbidden
> for use in home construction;

Because aluminum is a flammable metal? :-/ When aluminum is over driven, it burns with a flame temperature higher than oxy-acetylene? Because copper joined to aluminum forms an electrolytic and causes resistance, thus a voltage drop, thus a HOT SPOT where fires start? How does all this relate to the topic? By the way, since we are off topic anyway, application of a little silicone base grease to the junction of CLEAN copper and aluminum will remove oxygen, thus prevent the electrolytic action and THUS, you can then safely join cu and al.

> Now think about metal oxide semiconductor
> gates. 70 volts of static EMF across a feedline is nothing, particularly
> when you consider that a mosfet's gate is already tied to ground via
> a resistor or a transformer winding.

Surge of amperes will vaporize the resistor, regardless of how low it is (tho typically the resistor will be high in value, or in MY designs, abscent because I require maximum gain on my stages. Transformers couple surges (AC spikes) and a 1 to 1 transformer will present just slightly less than 70 volts on the secondary. The gap between the gate and the silicon junction in a MOSFET is only a few MOLECULES THICK! Just a few volts is enough to arc that distance, let alone 70 volts! Remember MOSFET stands for Metal Oxide, field effect transistor. The metal oxide is silicon dioxide, better known as glass. That glass has to be thin for the field effect to take place, too thick, no field, no biasing, no conduction. That's why MOSFETS are so sensitive on the gate, the dielectric material, in this case silicon dioxide, is so very thin and easy to break over with a penetrating arc-through.

> (And as has been pointed out by
> others, most mosfets are diode clamped anyway--yuck).

Best way to protect them is with fast switching diodes when
practical.

>
> Wrong again. ESD is *very* low current. Why do you think your wrist
> strap at an ESD work station has over 1 Meg Ohms of resistance to
> ground?

Oh, I don't know, OSHA requires it, because if you touch line
HOT, you will be killed if your left wrist is tied to earth ground, and
your right hand touches power line HOT. What is the discharge bleed
time for 10000 statcoulombs through a 1 meg resistor (keeping in mind
that the 1 meg looks very low but not THAT low to high voltage)? How
many ergs can one expect to shunt through 1 meg in 1 second?

> It works and it keeps you from being electrocuted in case you
> touch the mains. Apply Ohms law. ESD currents are on the order of
> microamps at best, not even milliamps. On a high performance front-end,
> even a Meg ohm resistor across the feed line is far preferable to diode
> mixers.

But diodes are prefered for higher gain so long as the signal
voltage is not high enough to turn the diode (read: ZENER) on.

>
> If ESD currents were of the order which you claim, then we would all
> be dead. Check out the biological effects of electricity. Current is a
> complete non-issue as far as ESD is concerned.

I don't know about you, but ESD has destroyed many computers,
many TV's, CD players, etc. I was standing right by my girlfriend when
she reached up and touched the CD player, pop, she pulled her finger
back, and the CD player was dead. Even with a 1k resistor pulling the
row address column address scan IC to VCC, it died. Now what do you
say? I'm sure EVERYONE here has at one time or another reached out,
discharged into an electronic device (computer keyboard, telephone,
whatever) and had it die, forever, from the discharge. Now how do
you argue that one? Hmm? Remember, everyone is watching. :) I touched
a joystick to a video game once, didn't hardly feel the discharge, and
blew the 6532 RIOT out. It has probably happened to MOST people. I
also remember touching a cheap telephone and discharging into it, and
the touch tone encoder IC blew. I'm sure everyone has done this at one
time or another, so you can't really aruge your way out of this one.

>
> Face facts, for a high-performance rx, avoid hanging mixers across a
> feed line. A neon bulb is preferable by far. In fact, I wouldn't even
> worry about ESD if the gate of the device I wish to protect has a
> reasonable path to ground--which means most any normal design.

My designs involve high input impedances. Why buy a device that
has 10 megs input if you tie it low with a 1 meg resistor, effectively
cutting it's potential down! Protect it by shunting just before it's
limits are reached with two back to back zeners of a couple of volts
and you will first protect the device, and second, avoid intermod....sq

>
> Thomas (ars KI4N)

I'm not a ham myself, I'm a professional electrical engineer.
I have a BSEE degree, and remember about half the theory, but ALL of
the practical, as I do this stuff every day on the job.............sq

John, you are absolutely correct on both points. We are not
concerned however with events taht generate electrostatic differentials
particularly, but the mechanical events which result in ESD (e.g., the
touching of the antenna by a charged body).

>
> A system "protected" by a bleeder isn't protected against a discharge due

Hmmm... single raindrop? :) I agree with you on your first
point tho, the bleeder will NOT protect from an ESD event.

>
> This is a hard problem to solve. Zeners and MOVs have been mentioned, but

Usually a zener only has a few picofarads of capacitance. My
ONLY gripe is that this capacitance changes with temperature! :(

> Ne bulbs, and their bigger brothers designed for lightning

> products.

914's are designed as switching diodes, but end up shorting out
with ESD. However, replacing a shorted 914 that gave it's life to
protect the MOSFET is easier AND cheaper. :) They can also only be used
where the signal voltage is at least HALF the bias on voltage (700mv)

> Reverse biasing the diodes with batteries or a quiet power
> supply helps.

That will reverse bias OFF the diode, but what about the varactor
effect? That will vary the capacitance of ALL diodes somewhat.

>

Sounds like (without looking) like a Sidactor (Digi-key sells
them). Sidactors are back to back zeners in one to-92 package......sq

(I use with great success, sidactors on all incoming port lines to the
embedded devices I build. I've never lost a component in one of my
designs to ESD, however, these are digital logic, not RF.............)

Why not? Maybe he's trying to come up with preservation techniques for old radios so they will play well into the future. We can't expect these tubes to be around forever. I say go for it and keep experimenting!

:
:John
:

It is very instructive to try to build solid state circuits that have the same characteristics (or better) as vacuum tubes.

I've built modules for replacing the tube mixers in my R4-C and its very difficult.

I've always thought that tube designs were much more elegant than modern solid state ones. Realize it took less than 20 active devices in the 1960's to produce a color TV. Now engineers can simply throw thousands of transistors at an application.

How many millions of transistors are in a new TV? The picture is really not much better- and most people never have their TV adjusted right anyway- too much color for pink and orange flesh tones.

So where is the progress? In more features and gizmos, just like the current state of commercial ham transciever manufacture.

Rob.

Source record: 94358

I 'd appreciate help from anyone who has experience designing superhet mixers and oscillators...

I have a ganged air variable with a 365 and 115 pf section and was hoping to use this for a multiband superhet...I know that for the AM band, with an appropriate choice of main tune inductance and oscillator coil inductance this air variable can track decently to yeild a 455 Khz IF. My problem is whether I can use the same capacitor for some of the short wave bands...even if that means I will have to change my choice of the IF.

Anyone have any suggestions?

:capsule?
:
:Regards, Anders

I believe that the low freq response of those mics is a function of their physical size and has nothing to do with the FET. I've taken some apart, and no coupling caps.

Because the Electret has such a high impedence, you would have to feed it with antenna ladder line :) to get enough impendence. With coax, the cap/unit lenght would severely limit the upper frequency. Maybe you would have a mic that would work from 50-1khz. :)

You may be stuck with dynamic elements, Rob.l

4656. Lithium-Ion Battery in a Standard C508A??????

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-01 00:00:00 UTC
From: miker <mreiney@NOSPAMhevanet.com>
Message-ID: <33694250.3319@NOSPAMhevanet.com>
Source record: 94360
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.equipment

Problem: Standard C508A works very poorly on NiCd batteries.
At 3V, the power is about 1/4 watt. At 2.4V it's about 60 mW.
NiCd batteries just won't cut it.

So, I thought I'd put in a Lithium-Ion Battery.
I'll use one cell and leave the other empty.
If I charge it at 100ma and limit the charging voltage to 3.5V, I won't exceed the rating of the transceiver.
According to the curves I've seem published on the web, I can get about 80-90% of the capacity between 3.5V and 3.0V. One Li-ion cell is about the same mAH capacity as the NiCds. Battery life is not an issue. Just need a little more than 60mw out.

Any flaws in this logic?

Anyone know where I can buy just one AA Li-ion battery at a reasonable price?

Thanks, miker

>intermod.

How about using the same system as used in CMOS chips. Connect one reverse biased diode from the input line to V+ and another reverse biased diode to V-. If the DC bias for the input is in the middle between V+ and V-, you have a quite large IMD free input voltage range. As noted previously in this thread, the capacitance varies when the reverse voltage over the diode varies, however if the input potential drifts, the voltage over one diode will increase while the voltage across the other diode will decrease, partially compensating for the capacitance change. The V+ line has to be well bypassed to the V- line at the operating frequency.

The V+ and V- lines also have to be well bypassed to ground close to the diode connection points with capacitors and zeners. If the ESD is flowing down the input line, it will forward bias one of the diodes and there must be a low impedance path from the V+ (or V-) line to ground through the capacitor and the zener in parallel. This will prevent the ESD to flow around the V+ and V- supply lines causing all kind of problems.

I once had a nasty surprise with this kind of protection in a high impedance circuit. I used 1N4148 diodes and they were sensitive to ambient light upsetting the input bias system. I had to cover the diodes to get away with this problem :-).

I built a simple 20 mhz digital scope that hooks to the parallel port.
Probably a lot simpler than anything analog you could do to make a
monitor into a scope...

Bottom line is that you can't change the horizontal sweep frequency
very much.

>whatever, rather than power). But you were a lot closer than him :)

He was speaking of LNA Gain. Half of 50dB is 47dB, but really I think
he was just trying to say was that even if the gain of the LNA fell
off dramaticlly, it would still have alot of gain. Don't beat-up on
Charlie, he's a good guy. The major danger in trying to modify the
LNA's is that you may cause them to become unstable, and the noise
figure will go to pot.

I think he is doing it as an academic "what if" exercise, to see if it
could be done. Besides, today's common tubes may start getting scarse
in another fifty years. And if the "solid state tubes" are built using
7 pin male plugs that fit the existing tube sockets, the AA5 radio
wouldn't even "know" it happened. Actually, 8 pin octal sockets are
more easily had, one could do a "tube" set for octal AA5's.

Item one was to protect the device. Question then arose as to
what if the incoming signal was above break-over. Then you'd get mixing
and intermod. I posted solutions which were to use higher voltage
devices (series diode strings or parallel zeners).

>
> Also, I thought that commercial gas discharge tubes were available for
> transient suppression? Don't they contain hydrogen, a very fast conductor?

Mercury vapor, a very fast conductor. Fast, however, is a
relative thing. Diodes switch in 10's of nanoseconds. Mercury vapor
devices and metal oxide varistors, etc., switch in 10,000,000's of a
nanosecond. Typically fast enough for old bipolars, but not for MOSFET.

4673. Electret microphone without FET transistor?

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-01 00:00:00 UTC
From: i3683@csc.dk
Message-ID: <5k9f1l$k7t$1@news.uni-c.dk>
Source record: 94428

I need some cheap low frequency, low noise microphones.
Electret microphone capsules are cheap, but they are generally not
low noise and not low frequency. They typically go down 50 Hz. I need
to go lower.

If I could find a source for electret capsules without the internal
FET, I could connect a low noise FET amplifier externally, and
conceivably make a lower noise, lower frequency microphone.

Does anyone here know a source on electret microphone capsules with
no internal FET. Alternatively a low noise low frequency electret
capsule?

I suppose it would work, but it may shorten the life of the battery.
You'd be better off building a simple charger. The one in the 1988 ARRL
Handbook p27-12 uses one LM723 chip and one transistor and works well for
me. I can keep it connected to the battery at all times, and be sure that
the battery is ready any time I want it without the risk of it being
overcharged.

Two possible ideas for this are the following 2 articles EDN Design Ideas
Aug 1, 1996 had a 3 IC superhet the only problem maybe finding the Plessey
ZN414 .
The second was a design using a Motorola MC3359 FM rcvr Chip, you use
the Quad detector as a product detector so you can pick up CW and ssb,
the article
was in QST Sep 1986. I have played with this design and have used a MC3371

in my last version, I haven't tried this but the 3371 has a Signal
strength output which could be used for AVC, and it looks like you could
use a Radio Shack
experimenters board to build it on, the 3371 requires a slight change
which you can see when you look at its data sheet. The data sheets come
from the Motorla
Web site, http//:www.Motorola.com.
I also used a MC3361 from a dead cordless phone to build one of these
recently,
I also salvaged the 455khz filter and other parts for this reciever from
the phone.

Source record: 94431

I came a cross an interesting book, "The Science of Radio" by Paul Nahin. In his introduction he explains why he chose to use vacuum tubes as the device with which he explains radio. "Transistors are two charge carrier devices (electrons and holes) understandable really only in terms of Quantum Mechanics. Electrical Engineering professors have, yes, invented lots of smoke and mirrors ways of 'explaining" holes in terms of classical physics, but these ways are all really, seductive frauds. They're good for their ease in writing equations and thinking about how circuits work, but even though they look elementary, I don't like to teach a first course in electrical engineering with their use. They are really shortcuts for advanced students who have had quantum mechanics."

What is Nahin talking about? Are all those descriptions of transistor operation that talk about holes really "seductive frauds"? Will we have to "understand" QM before we really understand transistors?

What do you guys think of all this? Should I stick with (understandable) vacuum tubes?

4679. WTB: Zilog SCC I.C. (4MHz)

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-01 00:00:00 UTC
From: k1el@aol.com
Message-ID: <19970501114300.HAA25064@ladder01.news.aol.com>
Source record: 94434

I am looking for a 4MHz version of the the Zilog SCC (8530) serial communications controller IC. Does anyone have any leads on these parts ?

Thanks, Steve K1EL

So how about a solid state 1L6 (or whatever the hard to get mixer
tube is for Trans-Oceanics)??? Make sure the input and output
capacitances match the Real Thing closely.

The reason you won't see that Mike is simple. The equations will not explain the answer.

We have limited means to measure the effects of radiation, and the very different induction fields.

We explain them by using the same terms, and that makes people think they are the same thing.

It's a lot like using two senses to explain fire, like heat and smell. Just because we might mix them in the right combination, it does not mean something is burning.

Shielding a small loop makes no more difference than replacing the loop with a single conductor of the same electrical characteristics as the shield. If the loop is properly constructed, the shield makes no difference at all.

In the real world, as others have stated here and as my own experience building dozens of loops for medical and receiving applications has indicated, shielding is a waste of time unless the noise is directly coupled into the loop instead of being radiated.

If the noise source is within a loop diameter or so, you might see a change. If the noise source is much further away than a small loops diameter, the shield almost always just helps support the antenna. ;-)

If that's the objective, Randy, then he'd be better off working on a 3-way portable and developing a solid-state 1R5, which would be closer to a 1L6 than a 12BE6 would be! A solid-state 1L6 would sell, a 12BE6 would have to be priced at about fifty cents to attract any buyers.

>Part 15 allocations. These bands are shared with the Amateur Radio Service.

I read the R&O, as well as the original NPRM, last night. The FCC has a pretty decent web site, though posting Word Perfect files and their ASCII output is not quite the same as HTML-izing.

>Under the new rules, very high gain antennas may be deployed at 2400 and
>5800 MHz. Certain transmitter power reduction restrictions apply at 2400 MHz
>but unlimited gain systems may be installed at 5800 MHz. These systems will
>enable high speed Internet access using unlicensed systems. You can expect
to
>see these systems deployed rapidly as soon as 1998 to provide non-commercial
>and commercial services on these frequencies.

To clarify: Very high gain antennas may be used in the 5800 MHz band but ONLY for "point to point" operation, such as wireless T1 links. Point to multipoint (access systems, pseudo-cellular, etc.) and sectorized (a bunch of directional antennas in a circle) systems are explicitly prohibited from using unlimited ERP; such systems are still limited to 4W ERP, and have to derate their transmitter power dB for dB when antenna gain goes up.

At 2400, it's 1 dB TPO reduction per 3 dB antenna gain increase.

These bands are ONLY for spread-spectrum use. Narrowband is prohibited at such power levels via spectral-density caps; if the bandwidth goes down, the power goes down too. However, frequency hoppers can dwell up to 400 ms on a sigle frequency, which can create noticeable interference to some kinds of narrowband operation. Direct-spread systems have no such effects.

The R&O actually makes a halfway decent primer on spread spectrum, in part because it discusses (and provides) new, clarified definitions for some of the terminology!

When I read these recent FCC rules, dollar signs swell in front of my eyes. Nice ones, not the boodlesque kind that so many govt. decisions display. Somebody is going to make money on this stuff. I wish I had the resources. Oh well -- anybody want to hire us for a consulting engagement? :-)

Bill,
I haven't read Mr. Nahin's book, but I'd suggest that anyone
who takes his approach in a TECHNICAL BOOK for the reason he cites
is either lazy or lost. I don't understand quantum mechanics, but
have designed a few bipolar and MOS widgets. I can also do the
non-linear analysis for an amplifier or oscilator. I don't leap tall
buildings and won't pretend to be smarter than Mr. Nahin, but I think
he's wrong here and you shouldn't waste your time with him. If he is
teaching an Electrical Engineering course with this book, he
shouldn't be (IMHO). If he's sticking to vacuum tubes in the course
of explaining something in a general science publication, then
that's his choice. Is "The Science or Radio" aimed at the
general reading public?

If you'd like a REALLY good treatment of RF circuit design
with bipolar devices that doesn't whine about quantum mechanics
(in fact, it doesn't even mention the subject) take a look at
Clark and Hess : "Communications Circuit Design" (the title might
be wrong, my copy is at work...) The book is out of print, but
it is a masterful treatment of the subject.

TWIMC

In my previous note, I may have been a little harsh. Make no mistake, I don't agree that students need an understanding of Quantum Mechanics to understand bipolar devices, but Dr. Nahin has written a book that according to www.amazon.com has an interesting looking table of contents. I've ordered a copy and will report back to the group. (At 19.95, it is at least worth a look. The table of contents suggest that the book is a systems approach to radio rather than a circuit design text. Personally, at that level of abstraction transistor circuits aren't any scarier than tubes, so I still don't agree with Dr. Nahin's choice here, but I'll keep an open mind.)

Check the book out...

If you want to understand *why* a transistor works, you need QM. If you only need to know *how* to use a transistor for practical purposes, you don't.

My opinion is that you don't need quantum mechanics to understand
transistors at a level quite satisfactory to designing very high quality
circuits with them. I'd certainly not waste my money on a course
which taught vacuum tube receivers or exciters.

There are a great many things we use that we don't need to know
the details of how they work to be able to use well. Do you know
how Teflon is made, and all the chemical reactions that go on to make
it? Do you know why from a chemical and physics standpoint it has the
electrical properties it does? If not, does that prevent your using
it in electrical designs? I suspect not. Does a lack of understanding
of exactly what life is, keep a doctor from saving lives??Z

Without knowing more about it, it appears to me that that author is
hung up on a detail that should never have been a concern in the
apparent subject matter, and he does a disservice to modern radio
practice by ignoring solid state devices.

> :
> :Don Wall

Why not? :-)... It doesn't trip my trigger to apply this to the
All-American 5, but it's fun to try.

I remember some folks in the 70's were selling direct plug-in replacements
that would even work with the full tube plate voltages. I have no idea
how well they worked.

I also remember various articles in QST in the 70's about solid-stating
your tube rigs, usually with plug-in approaches. There were suggested
approaches for various kinds of stages (usually using the hot new product,
FETs, so your tuned circuit impedances were still in the ballpark) -- I
think they expected you to change the voltage on these stages. One I
remember is for the Super Pro SP-600 receiver.

I myself have solid-stated an old T-368 exciter, and it's a nice
VFO/multiplier for 1.5-24 MHz. I went much further than plug-in modules,
though, with new circuitry/wiring for everything but the bandswitches and
tuned circuits. For anything more complex than that, I'd feel a little
odd about total solid-stating like this, though -- I think I'd want the
warm glow of the firebottles on a cold winter night while chatting on 75
meters...

Thanks to all those who responded to my question.

I really like Nahin's book. He is clearly someone with a love of radio and a desire to share his understanding of it. He is very humble in his approach - not at all "know-it-all." The book is full of interesting historical information about the development of radio.

In several chapters the math gets (for me) overwhelming.

Nahin starts out by saying that he's going to explain how a superhet receiver really works. He simply chose to look at a vacuum tube version, because he thinks that the theory behind tubes is simpler than transistor theory (I agree).

While I agree with the notion that we don't need to understand how the transistor works, I think the more you understand about radio, the more rewarding ham radio becomes.

Now , if Nahin is saying that you have to understand QM to understand the transistor, I guess he is saying that nobody really understands them! I remember reading about Feynman's saying that even he didn't really understand QED.

But how close to "reality" does the standard electron, holes, depletion region explanation come?

Before dismissing poor Mr. Nahin out of hand, I suggest you take a
look at his book. In my opinion, it's quite excellent, and I assure
you that in his writing Mr. Nahin does not whine and is neither lazy
nor lost. :-)

His book is developed from a lifetime of teaching. And I think he's
really saying that too many undergraduate and graduate electrical
engineering programs produce students who arrive at the conclusion of
a PhD program but cannot answer such questions as "How and why does an
antenna radiate?". (Mind you, I have a little trouble with that one
myself.)

Intended for students in the first year or two of an EE program, it's
an excellent mix of mathematical rigor and radio history. I found it
to be lots of fun when read for the history alone. (Someday I'll go
back and do the math!) Nahin places emphasis on "demystifying"
traditional radio topics and shows that they do in fact have a
mathematical basis -- but without diving down so deep in the math as
to be inaccessible to the "rest of us".

I recommend it highly for your bookshelf.

Regarding the question of discarding the study of solid-state devices, I'd reply "Certainly not!". The little beasties are extremely useful, even when (especially when?) deployed by the millions. It's just useful to remember from time to time that the models with which we work are really only approximations to reality, whether describing transistors or vacuum tubes. Nahin is trying to make us sensitive to that distinction.

Regards,

Mark McPherson

I like his book too - I picked it up a year or so ago after reading a review of it, and I'm a sucker for any book on radios. It's an interesting mixture of history AND mathematics - don't expect alot of circuits, though. The math is varied, and includes Fourier Transforms, Convolutions, and even the Hilbert Transform!

It's definitely a systems book, and provides a good mathematical foundation for the whys and hows of radio operation.

Regarding vacuum tubes - there actually isn't much mention of them in the book - they're really only discussed in a chapter titled, appropriately, "The Birth of Electronics," and this is the perfect place for their introduction.

- Jeff, WA6AHL

P.S. Way back in my University days, one of my Aged Professors (Prof. Silver - for whom I had a great deal of respect), lamented to us in class one day that engineering students were no longer taught vacuum tubes, but tossed directly into a sea of semiconductor physics, there to sink or swim. We all thought he was an old curmudgeon - after all, who in their right mind would design something with TUBES? But in looking back, I have to wonder if he wasn't right? For me at least the operation of a vacuum tube is so much more intuitive than that of a transistor - after all, we can all easily picture negative electrons boiling off the cathode, attracted by the positive plate, zinging like fast-balls through the grid which, as it becomes more negative, repells more and more of them. On the other hand, my mental pictures of transistors consist of potential gradiants and depletion regions, diffusion currents, and other diagrams which, unfortunately, have become fuzzy with time and lack of use.

4702. Monochrome computer monitor into a scope?

Soild state mixer/converter "tube" (ss12BE6) ideas: Build a differential pair of transistors, seperate bases, seperate collectors and collector resistors (both same value), tie emitters together. Suck a constant current from the node of the two emitters tied together. Bias both bases thru seperate resistors of same value. Bypass one to ground, couple the other to signal source. If signal transistor pulls more current, the other transistor gets less current, because the constant current sucker draws a fixed amount of current, and wont take more or less. And there's nowhere else it can go. This is linear for very small signal levels, if the signal gets bigger than a few millivolts, add resistors between each emitter and the constant current sucker. Op Amp people call this "degeneration" of the diff amp.

Any noise in the constant current sucker will manafest itself during times when one of the transistors is pulling much more current than the other one gets. You get amplitude modulated noise. If that transistor hogs 80% of the constant current, it also gets 80% of the noise, and if at 50% current, 50% noise, at 20% current, 20% noise. At least to a first order approx. Now, lets remove the noise and replace it with a single frequency continious wave oscillation. You get AM modulation. Or a hetrodyner, same thing, a mixer stage.

Buffer the antenna input to keep the input capacitence to 12BE6 specs, and maybe some signal gain. And build the oscillator to use the existing LC hartley circuit, and add gain to the mixer output (one of the collectors of the differential pair of transistors and make it high impedance to drive the IF transformer.

This is getting to be a lot of stuff, but the 12BE6 tube was a complex design that was made easy and cheap to manufacture. It could be though of as a "vacuum IC".

Actually, hydrogen is not all that dangerous, especially if it
is produced "as needed" for the process by electrolysis of water. Many
industries, two of which are the production of vegetable oil, and the
basement "dope lab" production of methamphetamine, use hydrogen gas in
their process. However, a dope lab can substitute lithium anhydride for
hydrogen/catalyst/parr apparatus methods. Lithium anhydride is the guts
from a lithium battery, fyi.

However, hydrogen isn't used in thyratrons. However, if you
ionize hydrogen, you get a nifty glow. Hydrogen is only explosive when
mixed in the proper ratio, 2 hydrogen to 1 oxygen, and ignited by
discharge, heat, or flame. Hydrogen can be used in ionizing laser tubes
as a moderator gas, subject to intense ionization and plasmazation....sq

I think I mentioned the "varactor effect" in a previous message.
This will work, but typically, from my experience, capacitance of the
protection diodes are not that big of a deal. It's not like they are
used in the _mixer_ stage or anything. :)

The photodiode effect. :) Package NOT thy semiconductors in glass, lest ye be wanting photonic effects. ;) The 12th commandment of electronic component engineering. ;) You should try playing light upon an erasable EPROM version of the 8051 microcontroller sometime! Some of the gates don't like light AT ALL, and they typically act goofy, freeze, or even dump and lock up when they see enough light. That's why I cover the windows on those with BLACK TAPE, and not white paper stickers. White paper may block UV for erasure, but it doesn't block the IR which is the band that affects the logic circuits inside.

Did you know they make black epoxy diodes in the same price range as the 1N914 whereby you could eliminate the photonic effects? Just buy 1N4001's and swap them for your 1N914's in the circuit....sq

I have been wondering about this from the standpoint of antennas.

If the aluminium/metal bond oxidises with time, which it surely must do if outside, what happens to the RF performance of say, a yagi, that assumes the boom and elements are connected?

Perhaps the capacitance of the oxidised junction is enough to make it still work?

There might be a grounding implication and static build up problems as presumably, although the dielectric strength of the oxide is high, the thickness is only a few microns.

>myself.)
>

Mark: I bought Nahin's book because it looked like it woul provide a pretty good presentation on the mysterious subject of why antennas radiate. While he put out a lot of useful info, I was a bit diappointed by his presentation on this subject. I thought his explanation of current distribution on a quarter wave antenna (current "shunting off" through distributed capacitance to ground?) was kind of wierd.

Nahin: " I went to a good undergraduate school with fine professors who showed me how to cram my head full of all sorts of neat technical details; but when I received my first engineering degree I still didn't know at the intuitive, gut level what the devil was really going on inside a kitchen radio. That, like my thickening girth and thinning hair, came with time."

That's the kind of understanding I'd like! Gut level! That's why his "seductive fraud" comment about transistor theory was a bit worrisome. I thought I'd come to understand how the transistors work!

One other comment: On the "how antennas radiate" question, I think the textbooks too often sell the reader short by saying "if you can't handle the differential equations you really can't understand how the antenna radiates." I disagree. I think it is possible to come to a "gut level" understanding of EM radiation without really dominating the math. We can take our inspiration from Faraday!

> (understandable) vacuum tubes?

Do you really think that vacuum tubes are "easy" to understand? They are more complex than any of us can imagine. Einstein got a Nobel prize for his work of vacuum tubes (photo-electric cells).

Nevertheless, we understand vacuum tubes "well enough" to use them and design circuitry. The exact same situation is true with transistors.

You don't have to be a super-scientist to *design* a high quality one-stage bipolar audio amplifier. As a matter of fact, all you need is a transistor data sheet, and an understanding of what the data sheet means in terms of device principles at a "macroscopic" level (junction behavior and carrier flow).

A knowledge of quantum electrodynamics and electromagnetic principles is just as important for a deeper understanding of vacuum tubes.

I think that particular author is incorrect.

Mike, I second Woody's motion on the synchro/motors. I happen to have had at one time (I think I still have them) a pair of them that run on 120V/60Hz. My Dad used to work at a shop that made stuff for the Military and I think these came out of a radar-based gun sight. As I recall they're very smooth running and precise, and very difficult to "unsynch." I'll try to dig them up this weekend (they should be _somewhere_ in the basement). If I can find them, they're yours.

I agree. I recall a variation of the Electret microphone, called the "PZM" (Pressure Zone Microphone), that was popular several years ago. It was mounted in/on a square plate, about 5" X 5". For best low frequency response, it was recommended that it be mounted on a larger surface.

Perhaps the PZM technology would have a frequency response low enough to meet Anders' needs.

: I agree. I recall a variation of the Electret microphone, called the
: "PZM" (Pressure Zone Microphone), that was popular several years ago. It
: was mounted in/on a square plate, about 5" X 5". For best low frequency
: response, it was recommended that it be mounted on a larger surface.

I believe you will find that the low frequency response of a capacitor mic is determined by some other factors: the main one usually is the capacitance and the preamp input impedance. Obviously, smaller mics would generally have less capacitance, so that's a factor, but if you can get a higher preamp input impedance (up to where the insulation in the mic shorts things out), you can get to lower frequencies. I'm not sure how realistic the expectations of the original poster are with respect to improvement, though. I think the fets used in the cheap capsules aren't too shabby. You can get to better response with instrumentation capacitor mics, but then you are up in the $1000 range right away. (A lot of our customers use capacitor mics for acoustical measurements.)

> supply?? any info +or- is a help thanks
> craig

Probably won't work. I suspect it is a linear supply which means
that there is a bulk DC supply before the regulator of 8-10V. With
this configuration, the output must be lower. You could get 6 volts
out of it, maybe even by adjusting a pot on board. A 15 volt supply
could be adjusted though.

However, if the bulk supply is a two diode full wave supply, it
may be possible to do this. Keep in mind the amperage will be
halved, and be sure the capacitor can handle it (need be 25V).
Then the divider circuit to the regulator can be adjusted. To do this,
you need to remove the center tap, and place the two outer leads
of the xfmr to the ac input of a bridge rectifier. Get one that is
about 100PIV, 5 to 6 amp. Then hook the + and - to the filter
cap. Then maybe you can do this.

Hope this helps

4721. NHRC-2 Repeater Controller Review

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-02 00:00:00 UTC
From: Jim Devenport <jdport@concentric.net>
Message-ID: <336A159B.7B45@concentric.net>
Source record: 94394

I have just finished installing and setting up the innovative and relatively inexpensive NHRC-2 Repeater Controller and would like to share some of my observations:
Negative Comments:
-I was disappointed that the pots (CW ID tone level, master audio level, etc) were not labeled on the board. I had to mark them myself with a magic marker to ease level setting stress.
-There is NO I/O available from this controller except for repeater PTT. Most controllers have at least one or 2 I/O functions available for controlling CTCSS, etc, but no such thing with this board.
-I was disappointed in the temporary nature of the 4 "ID" voice message buffers. While maintaing the recorded voice audio through power disruptions, if you mess around with many of the controller settings, it will summarily forget all voice messages in storage. Just enabling the simplex repeater mode will erase all voice storage.
-No method is available for shortening the required 8-digit sequence required to change ANY setting. For instance, to set the CW ID, EIGHT digits must be entered for EACH character and digit being set up for the callsign ID etc. That's a long string of DTMF tones to send...
-No simpler "user" functions are available, such as a simple DTMF entry to activate the "announcement" voice message about the latest club meeting, etc. You have to use the SYSOP password and the user function code (again, 8 digits) to activate any of the messages, and this is hardly information any sysop wants the general public to have.
-No function exists to tell the controller to "read back" to the sysop what current settings are set up. You can enter a function but cannot tell what it is before you enter it.

Good features I like:
-All functions are able to be set via DTMF entry.
-Small size and low current drain
-Surprisingly good voice quality in the digital voice storage (this can be a DISadvantage if a known ham is used for the voice ID, it will invariably result in someone calling him/her to "chat" almost every time the ID occurs; if the ham doesn't respond, the caller sometimes gets annoyed as if the "ID'er" is ignoring him)
-Very satisfactory message length in voice storage, using simplex rptr mode is a lot of fun and very useful when setting up or testing, and "conversational" transmissions are possible.
-Even in simplex repeater mode "kerchunking" the system will get you a satisfactory "squelch tail" indicating there is a live repeater listening, so users don't get excited and think the repeater has died. In other words it acts very "normal" while in simplex repeater mode.

All in all, I really enjoy this controller, my main complaint is its
lack of auxiliary input/output (I/O) functions.

It would be very bad, *if* you didn't use the compound supplied with the
antenna for use in the slip joints. This compound, trade name NoAloX,
is a conductive grease. It seals the joint from air so that the oxide layer
cannot form. This usually comes in little plastic squeeze ampules from
the antenna manufacturers, but you can buy it in bulk from your local
electrical supply house. It is required for aluminum house wiring.

20 years is young for a vacuum variable that has not been mistreated.

You can build a simple 12vdc high voltage source using a flyback tranformer and one 2N3055. There is lots of info on the web under "Solid State Tesla Coil" or variants thereof.

Also, there are commercial coils used for testing vacuum leaks in chemistry apparatus. Try Fisher Scientific. If you can take it to hamfests, you are at a big advantage.

>:>
>:Why would you want to do that?

Actually a shrewd marketing move IMNSHO since it demonstrates the ability
to do so. Something like a 200 mph Pinto would impress more people than
the same Thunderbird.

Add in the fact that an AA5 radio will typically be much more tolerant of
minor differences that a TransOceanic on 16m plus the fact that a minor
error causing max smoke would not result in much of a loss and the use of
that platform as a technology demonstrator makes a lot of sense.

Would be surprised if any SS tube could be sold for less than $25 so that
is really not a factor. Of course the gentleman might just have wanted to...

All Motorola software is Licensed.
You must sign a license agreement with Motorola or face
criminal prosecution. And BOY do they prosecute!
Their attorneys are constantly finding software violators
and when they do they are neither kind nor merciful.

Suggestion: Just buy the software from them directly. 800-422-4210
The software may be expensive, but after all it comes
nowhere close to paying an attorney or legal fees.

BTW: I am NOT employed nor am I a representative of Motorola.

4730. Dead TS50s digital board question.

Hi Anders... as has already been said-more or less-the other name for
an Electret mike w/o the FET is a: condenser microphone. It seems to
me that one of the surplus dealers was selling high quality condenser
microphone elements the last time I looked through their catalog.
Problem is: I don't remember which. It could have been Hosfelt
Electronics I think. Try them and see. If not, maybe M.P. Jones, or
All Electronics, or Altronics. It almost certainly WAS one of those.

Eimac type YC156. This is the same basic tube as a 4CX5000. It is a high mu triode with beam forming cathode and grid that provides the gain of a tetrode. Power gain is 15 db.It was designed for the medical industry and has a rating of 6500 volts at 4 amps (67 amps peak in pulse mode !) This tube will operate with full output to 110 Mc. No socket is necessary for this tube, it will mount in a 3 1/2 inch diameter clear hole, and the grid ring will bolt to the chassis. Height overall is 8�.
I have all data sheets. Tubes are used but emission is guaranteed for full output. $325 each.

> photomultiplier tube, thanking you in anticipation, Gerald VK4ZSG.

The 1P28 has a Cs3Sb (cesiun-antimony) photocathode. It has a narrow spectral response with a peak responsivity of 5.5mA/Watt @ approx 425nM. Responsivity is down 50% at 375nM and 575nM (approximate).

Burle Industries purchased the PMT business from RCA some years ago and still makes them. http://www.burle.com/ Ask for a copy of thier "Photomultiplier Handbook" for applications information and all the theory you will ever want to know.

Hello colleagues and friends
I have a tuner MFJ-945D the which it has the problem of that it lacks the BYPASS button that allows to don't use the tuner although this in it line. My problem is that or else I want to use the tuner I have to remove it. I would like to include a BYPASS button in order to could tune or not to my will. I could utilize the external switch for ON OFF the light of the SWR meter, but do not know how to make the interior connections. (I Believe that a posterior model 945E include this function). Thank you ahead of time for yours helps.
Another doubt that I have is that I own a vertical antenna for WARC bands and do not know which that mark it is. It has an aluminum inferior part for 24Mhz, then a reel for 18Mhz consecutive from an aluminum piece and then another trap for 10Mhz consecutive lastly of another aluminum piece. I have put a radial for perpendicular strip to the antenna but in 18Mhz don't succeed in having less of 1.8 or 2 swr, for more than I lengthen or I cut the radial. I have good SWR in 18,500, but although I lengthen the ground radial I don't get that down to 18.140 for example. If you could tell me the brand of this antenna is this and their characteristics or how I could make it resonate well and which height is good for the aerial to stay in.

I wait for yours answers and aids.

Dear friends I have one question and want you to help me. I
own a Icom 706 rig and two sticks for 20 and 40 meters. The
antennas are Valor Pro-am 3/8" conectors and they provide me
very good performance when used with a single magnet mount
on the roof of my 1990 Ford Fiesta car. The problem is that
I can not use it when moving the car because of the poor
catch (streght) of me magnet mount. I have tried several times to
mount the aerials in a hatchback mount, but performance and
SWR are very bad indeed. I do not know how to improve it or
how to use it on the move. The aerials are almost 2 meters
long, half helicoidal half steel stick.
Also will be wellcome any mods, commnets, improvements or
anything about the ICOM 706 rig, how much power can it run,
etc.
Any commnets and improvements for an old ATLAS 210X will be
wellcomed. I will apreciatte also comments on how to install a
vertical aerial for WARC bands which has two traps (coils). Which will
be the best height for best performance? How can I get the best SWR ?
How long and how many and which angles must I need for radials for 18
and 24Mhz ? (As I do not expect to use the 10Mhz band). Will it
perform better on 18 and 24Mhz than my windom aerial for 10-80 metres
which is at 3 metres over my roof which is in the top of a 40 metres
high building?

Sorry for my English, thanks for your help.

>upon an erasable EPROM version of the 8051 microcontroller sometime!

So they still have that problem. In the early days of EPROMs, a big official international delegation was on an industry visit and the new system was shown to the distinguished guests. There was a lot of media people present and some photographer took a picture of a card and the photo flash zapped one EPROM and the system went down in front of all the quests. Very embarrassing. Since then their policy has been to cover the EPROM window :-)

> Did you know they make black epoxy diodes in the same price
>range as the 1N914 whereby you could eliminate the photonic effects?
>Just buy 1N4001's and swap them for your 1N914's in the circuit....sq

Well, there are a few minor details to consider, the switching time for 1N400x series is measured in usecs, while the 1N914/4148 it is usually quoted in nanosecs. The ESD discharge times are usually below 1 usec. Also just wondering what the capacitance range for the 1N400x series might be. Didn't some kit maker use it as a varactor in an HF-oscillator.

The reverse leakage for 1N400x is quoted in uAmps, while nanoAmps are more typical for switching diodes. This may upset the circuit bias and add an additional path for the power supply noise to sneak into the input line.

Returning back to the original tread about active antennas, it looks like some kind of current limiting would be preferable between antenna whip and the gate of the source follower so that the protecting diodes (any configuration) could survive, since the ESD current can be several Amperes in the worst case. Putting a series resistor between the antenna and amplifier has the drawback, that the thermal noise

generated by the resistor is in series with the antenna voltage. For 1 kohm and 3 kHz bandwidth at room temperature, the added noise voltage is 0.2 uV and for 1 Mohm 7 uV. This might or might not be a problem, depending on the background noise level picked up by the whip.

friend asked me if this was legal.
I told him that I would review it and get back to him. When I first
read
the letter my new client brought me I thought it was some off-the-wall
idea
to make money. However, a week and-a-half later we met in my office to
discuss the issue. I told him the letter he originally brought to me
was
not 100% legal. I suggested a few changes with which the letter would
be
100% legal.

I was curious about this letter, and my client told me how this plan
works
and suggested that I give it a try. I thought it was a long shot and
would
be a waste of time, so I decided against participating.

However, before my client left, I asked him to keep me updated of his
results. About two months later he called me to tell me he had received
over $800,000 in cash!!

I didn't believe him, so he suggested that I try this idea and find out
for
myself. I thought about it for a couple of days and decided that I
didn't
really have anything to lose, so I asked my client for a copy of the
letter. I followed the instructions exactly, sent out 200 copies, and
sure
enough, the money started arriving! It came slowly at first, but after
3
weeks, I was getting more mail than I could open in a day! The money
stopped
coming after about three months. I kept a precise record of my
earnings,
and
they totaled $968,498.00!! I was earning a good living as a lawyer, but
anyone
in the legal profession, or even anyone who owns their own business will
tell you, there is a lot of stress that comes with the job. I told
myself
that if things worked out, I would retire from my job and travel. I
decided to try the letter again, but this time I sent out 500 letters.
Well, three months later, my earnings totaled $2,344,178.00!!! I just
could not believe it. I met with my former client (and now my friend)

for
lunch to find out how it worked. He told me there are quite a few
similar
letters going around.

What made THIS ONE DIFFERENT WAS THE FACT THAT 6 ADDRESSES APPEAR ON THE
LIST, AND NOT 5 LIKE MOST OF THE OTHERS. This fact alone results in
your
name being on far more returns. Of course I was thankful that he had
shown
this plan to me, but he was just as thankful that I had suggested the
changes to ensure that this plan was legal since most people don't want
to
risk doing something illegal.

I'll bet that by now you are curious to know the little change I
suggested
in my friend's original letter. Well, if you sent a letter like this
out,
to be legal you must actually sell a product or service if you expect to
receive a dollar. I told my friend that anyone sending a dollar back to
him must receive something in return. You have received this letter due
to
the participation of each of the 6 persons given below. This letter and
the plan given within this letter are a "product" that you have
received.
Thus, you will be sending $1.00 USD to each of the 6 persons given below
in
exchange for receiving this letter and for asking them to provide the
"service" of adding you on their mailing list. THIS IS A SERVICE AND IS
A
100% LEGAL BUSINESS OPPORTUNITY WHICH IS COVERED IN TITLE 18, SECTION
1302
AND 1342 OF THE POSTAL AND LOTTERY LAWS.

NOW, PLEASE FOLLOW THESE TRIED AND TRUE STEPS TO OBTAIN THE AMOUNT YOU
DESIRE: Immediately send a $1 US dollar bill to each of the 6 people on
the list below. Wrap this dollar in a note with the words: "Please put
me on your mailing list." (Remember, in this way, you're not just
sending
a
dollar to someone; you're paying for a legitimate service.) Include
your
address. You do not need to include your name if you don't want to.
This
is
the key to the program!

Make sure that you retain EVERY name and/or address sent to you, either
on
computer or hard copy, but do not discard the names and notes that

people
send to you. This is PROOF that you are truly providing a service, and
should
the IRS or some other government agency question you, you can provide
them
with

this proof! Therefore, you will start a list of all the people who send
you a
dollar requesting to be added on a mailing list. Actually, you will
want
to safeguard this list because it can generate even better responses and
much more money later!

See step #4 below.

Remove the #1 name on the list, and move the rest of the names up one
position. Then place your name in the #6 spot. Thus, #6 becomes #5, #4
becomes #3, etc., and YOU will be #6 on the list. DO NOT EDIT THIS
LETTER
ANYMORE BEYOND THIS POINT. If you are mailing this letter, you may edit
the reference to the Internet.

Post this letter in at least 250 newsgroups, I do 30 groups per post.
You
can simply copy the contents of this letter and post it to the
newsgroups
of your choice. (If you're not sure how, see my directions
at the bottom.)

IMPORTANT NOTE: Please pay attention to the newsgroups in which you
post.
If there is an abundance of similar letters, you may want to seek
another
newsgroup. Thus, pay respect to the harmony of the newsgroup and use
common sense. There are plenty of newsgroups on the Internet. (I
think there are close to 18,000 of them.) ALSO, PLEASE POST IN
APPROPRIATE
GROUPS AND SPREAD YOUR POSTINGS OVER MANY DIFFERENT LOCAL &
INTERNATIONAL
AREAS (SPREAD THE WORD) !

Keep a copy of this letter so you can use it more than once. Also keep
EACH
AND EVERY NAME AND ADDRESS SENT TO YOU as instructed in #1. Then, send
out
more copies in about 6 months, but mail it to the addresses you received
(your new mailing list) with each dollar! It will work again, only much
better! Here are the addresses that you must send a dollar to with your
slip of paper requesting placement on their mailing list, as instructed
above:

1. F.P. Tine
1 Pine Glen Drive
Sickerville,NJ 08081-1319
USA

2. Robert Greene
Rt 3389

****
* D I R E C T I O N S
*
* How to Re-Post
*
****

OK. This is how I did it (Windows95/PC). Do not re-type this
email (as this post previously instructed). First, open up an
empty Notepad file. (In Windows it should be under the
Accessories
menu.) Then, put your cursor at the beginning of this document,
hold the left mouse button down, drag it to the bottom and
release.
Now hold the Control key down and press 'C' (CTRL-C). This will
copy the highlighted text to the clipboard. Now get back to
your
notepad file (in Windows95 it's down in your taskbar), put the
cursor at the top of the notepad file, then hold the control key
down and press 'V' (CTRL-V). This will copy the contents of the

clipboard into your notepad file. Now you can edit the file.
Don't forget to remove name #1, put your name in at #6 and
re-number
accordingly. Save this file (as a .txt file.) If you want to
break up your sessions of posting you'll always have this file
to go back to.

FOR NETSCAPE USERS:

1) Click on any newsgroup. From a newsgroup, click on the 'TO
NEWS'
button, which should be in the top left corner of the newsgroups
page. This will bring up a message box.

2) Fill in the Subject.

3) Highlight the entire contents of your .txt file, do a CTRL-C to
copy
the document into the clipboard, get back to the e-mail you are
posting to the newsgroup and press CTRL-V to copy your file into
the
body of the e-mail.

4) Hit the 'SEND' button in the upper left corner. You're done
with
your first one!

5) Go to another newsgroup, press 'TO NEWS' button, type in the
Subject
line, press CTRL-V, press 'SEND'. That's two! Repeat as
needed...

INTERNET EXPLORER USERS:
(Directions are pretty much the same, except for the names of the
buttons.)

1) Go to newsgroups and press 'POST AN ARTICLE'.

2) Fill in the Subject.

3) Same as #3 above.

4) Hit the 'POST' button

4740. Re: Electret microphone without FET transistor?

Newsgroup: rec.radio.amateur.homebrew

In article <5kd7si$72m@hpcvsnz.cv.hp.com>, tomb@lsid.hp.com says...
>I believe you will find that the low frequency response of a capacitor
>mic is determined by some other factors: the main one usually is the
>capacitance and the preamp input impedance. Obviously, smaller mics
>would generally have less capacitance, so that's a factor, but if you
>can get a higher preamp input impedance (up to where the insulation
>in the mic shorts things out), you can get to lower frequencies.

I agree to that.

> I'm
>not sure how realistic the expectations of the original poster are
>with respect to improvement, though. I think the fets used in the
>cheap capsules aren't too shabby.

The lettering on the transistor inside the electret microphone, that I
took apart, was Q169. I am not familiar with a transistor of that name.
Does anyone know this one?

>You can get to better response with
>instrumentation capacitor mics, but then you are up in the $1000 range
>right away.

True. Having destroyed a few of the $1000 microphones, I feel a need for
a cheaper type of microphone. Perhaps a homebuilt capacitor microphone
10 inches in diameter would be more realistic than modifying the small
electret microphones. I could achieve a higher capacitance, and I would
not need an amplifier with > 100 Mohm input resitance.

Regards, Anders

The same quantum mechanics that describes conduction in semiconductors
also describes conduction in a copper wire. No one I know of says you have
to understand quantum mechanics to learn Ohm's Law or Kirchoff's laws in
elementary Physics.

wasn't the quantum mechanics used at school for an excuse that the
teachers did not have anything more practical to tell us?? Several of
the stupidities we had to learn has later dissappeared!

Has anyone ever tried using a speaker with whizzer cone as a mike? You should get great low freq response.

I've used them before just for experimenting sake. You need an preamp or input designed for a dynamic type mike.

Rob.

Hello to all,

Re: Strictly 6 web page.

I have now included a list of all known 6 meter capable radio's, with
hyperlinks to relevant info on the net.
Hope you find it useful!
There is also a new section on homebrew- do you know of any homebrew links
I can add to this section? needs to have 50Mhz/VHF content.

Cheers...Jim VK1ZFG

> cover the EPROM window :-)

I have always been paranoid about exposure of the die to light
after programming, as the erasure is a linear thing, and at some level
of light exposure, the EPROM becomes "stupid" and will give ambiguous
bit values, SOMETIMES! This can lead to major hair-pulling! However,
I discovered that ambiguous code values (which result typically in
lock-up or output data errors) can be induced with heat, and REduced
with cold, thus diagnostics of this failure are pretty simple.

Just so everyone who is unfamiliar with flash/Eprom reactions,
the flash will cause the Eprom to become stupid, locking the CPU, but
a simple reset will return things to normal, and there shouldn't be
any permanent damage to the data burned into the Eprom.

> HF-oscillator.

1N400x series diodes (in my opinion) are fast enough for ESD.
I mean, they use MOV's for ESD protection, typically! :) The
capacitance of 1amp rectifiers shouldn't matter much, it would be the
bigger 4amp or higher diodes that would have sufficient variactor effect
to cause problems, but if your power supply is stable, can be "tuned out"
and forgotten about.

This is usually true, but there are higher quality rectifier
manufacturers out there. Look for mil-spec, and you're WAY ok. ;)

From: J M Noeding <la8ak@online.no>
Message-ID: <336BBF25.39B0@online.no>
Source record: 94320

Hi
I made a halfwave notch filter of RG214 for 288MHz (quarterwave for 2m), but the notches seems too sharp. I rather use LDF5-50 (7/8" cable) for better power handling, but I need some technique to widen the notch responce. The notch depth was somewhere about 33dB. I need two cable notches with quarterwave line in between to improve my 144MHz linear amplifier second harmonic suppression

Not a good idea, 4001s have way too much capacitance, and they switch
much more slowly because of it too...but fast signal diodes do come in
black epoxy too, all the SMT ones are that way except for some of the
old style MELFs.

Jim

4749. Please help with VHF FM Crystal Filter bandwidth specs.

If Motorola would support their products like other radio mfgs, they wouldn't have a software pirate problem. King, (sub) Standard, and many others only charge minimal fees for software or will post on their bulletin boards for free! I know many shops who have sent in radios for repair only to find it was re-programmed with a newer ver. software and now the shop has to bend over and purchase MORE software just to be able to program a radio they have owned for years! Or one city PD that purchased a large qty of Mots and needed several versions of software to program identicial radios in the same shipment. I have seen more than one radio dealer financially ruined by Mot for software infringment. My personal opinion is SCREW Motorola!!!!! I wish someone out of the country would post the software on the internet so everyone can have it free, and make those big Motorola lawyers squirm.

The antenna may detune and/or become intermittant. The best bet is to coat each joint with no-ox (or products by other trade names that are avaliable at your local electrical supply house for use with aluminium electrical wiring. It also makes it a lot easier if you ever have to disassemble the antenna!

As I recall, they used about 3v on these mikes...try increasing
voltage to 5 volts for better output and response.

4757. Galena crystal??

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-04 00:00:00 UTC
From: Ray LaRue <raylarue@gte.net>
Message-ID: <5kihto$6gm$1@news7.gte.net>
Source record: 94330

Recently found my original Cat's whisker crystal holder, less the crystal. This was my part of my first "radio" many years ago. Would love to find another crystal and build a set, to show my kids and grandchildren. Anyone able to suggest where I might get a piece of Galena? The holder looks like it takes a piece about 7/16" in diameter. Thanks for any help you can offer.
73,
Ray, W4BYG

Why do all the royalties always go to Motorola and not the real creators of
the work?

You can talk all day about "work for hire" but I still think all the talk
about intellectual
property rights is just another money grab by large corporate interests.
There would
be NO talk of this if software creation was treated like an art, with such
common
niceties as CREDIT to the actual writers, and ROYALTY agreements. A
multimillion
dollar movie credits even the manufacturers of the film and cameras, but in
a similarly
sized software project any credit to anybody is hidden, at best.

This ended up being cross posted. This is easy to inadvertently do, as
most mail
programs simply copy multiple group postings in subsequent postings and
replies.

Until the mail programs change, you will see this happen a lot. Not really
a big
deal. Do you really think a glitch this small ruins a newsgroup?

Call Antique Electronic Supply in Tempe Arizona at 602-820-4643 and ask
for item P-Q111 galena crystal, also P-H415 cat whisker, if you need it.
Have them send you a catalog.

Ray: Antique Electronic Supply stocks them.

AES
6221 South Maple Avenue
Tempe, Arizona 85283

Tel: 602-820-5411
FAX 602-820-4543

I built a Crystal radio with Galena from AES. It was a lot of fun and
very educational. I'd heard about having to find a sensitive spot on
the crystal, but until I actually had to do it I didn't really
understand. Once I got the receiver together, I had to control the
urge to build the corresponding spark transmitter!

73 Good luck. Bill N2CQR

Sure.

First it is just as easy to pay attention to where things are going and
erase the newsgroups that have nothing to do with the subject.
Inadvertant is really inconsiderate.

This is a small ng but why does that mean it can't be "pure". That was
one of the things that was discussed when this ng was born. Postings
that are not "on topic" are a waste of bandwidth and space in my
computer and on the server. How much is wasted when the sender posts
the article across the entire spectrum? A lot.

What it boils down to is that this ng was dedicated to DX. Not FS, not
WTB, not Help my toaster is burning when I'm on 15 cw, etc etc etc.....

4766. Re: Transistor Theory - seductive fraud?

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-04 00:00:00 UTC
From: Mark McPherson <markm@teleport.com>
Message-ID: <336D226F.9C937808@teleport.com>
Source record: 94339
Body handling: HTML body converted to readable text

Bill Meara wrote:

Mark: I bought Nahin's book because it looked like it woul provide a

pretty good presentation on the mysterious subject of why antennas

radiate. While he put out a lot of useful info, I was a bit

diappointed by his presentation on this subject. I thought his

explanation of current distribution on a quarter wave antenna (current

"shunting off" through distributed capacitance to ground?) was kind of

wierd.

Nahin: " I went to a good undergraduate school with fine professors

who showed me how to cram my head full of all sorts of neat technical

details; but when I received my first engineering degree I still

didn't know at the intuitive, gut level what the devil was really

going on inside a kitchen radio. That, like my thickening girth and

thinning hair, came with time."

That's the kind of understanding I'd like! Gut level! That's why

his "seductive fraud" comment about transistor theory was a bit

worrisome. I thought I'd come to understand how the transistors work!

One other comment: On the "how antennas radiate" question, I think

the textbooks too often sell the reader short by saying "if you can't

handle the differential equations you really can't understand how the

antenna radiates." I disagree. I think it is possible to come to a

"gut level" understanding of EM radiation without really dominating

the math. We can take our inspiration from Faraday!

73 de Bill N2CQR

Bill, I know what you mean about "gut level" understanding and you've
inspired me to go back and read what Nahin has to say about antenna radiation.

I did find the passage which originally inspired this thread. It
can be found on page xvi of "The Science of Radio", in a sidebar entitled
"Three Pedagogical Notes":

"When the writing of this book reached the point of introducing electronic
circuitry (Chapter 8), I had to make a decision about the technology to
discuss. Should it be vacuum tubes or transistors? Or both?
I quickly decided against both, if only to keep the book from growing like
Topsy. The final decision was for vacuum tubes. My reasons
for this choice are both technical and historical. Vacuum tubes are
single-charge carrier devices (electrons) understandable in terms of "intuitive",
classical freshman physics. Transistors are two-charge carrier (electron
and holes) devices, understandable really only in terms of quantum mechanics.
Electrical engineering professors have, yes, invented lots of smoke and
mirror ways of "explaining" holes in terms of classical physics, but these
ways are, really, seductive frauds. They're good for their ease in
writing equations and in thinking about how these circuits work, but even
though they look elementary, I don't like to teach a first course in electrical
engineering with their use. They are really shortcuts for advanced
students who have had quantum mechanics. From a historical view,
of course, it was the vacuum tube that made AM broadcast radio commercially
possible, and to properly discuss the work of Fleming and De Forest, the
vacuum tube is the the only choice. And finally, students should
be told that the small-signal equivalent-circuit model for the junction-field-effect
transistor (JFET) is identical to that for the vacuum tube triode!
Plus ca change, plus c'est meme chose."

And how can you not like a textbook author who cites Garrison Keillor and
Woody Allen as spiritual influences???

Somewhere I have a copy of a nice paper on electromagnetic radiation which
is essentially a non-mathematical treatment involving current and charge
distributions on antennas and the corresponding behavior of their associated
electric and magnetic fields. I'll try to dig it out and post the
reference for you.

Me, I still think about transistors in terms of a model I learned long
ago from a very good analog IC designer named Jim Dunkley. A very
advanced and technically-savvy guy, his instructional model for bipolar
transistors involved (as I recall) a giant box of ping pong balls with
a slot on one wall which could be raised and lowered, a tilting conveyor
belt below the slot with ping-pong-ball-sized holes in it, and a large
hopper. :-)

I suspect Nahin would not approve!

All the best,

Mark McPherson

If you work for a corporation and develop software or other intelectual property on company time, the results belong to the corporation. They are paying you for your time and deserve the results of your work. Think of it as working in an auto plant. Since you installed the windshield, does that mean you get to take the car home with you?

If you wish to keep the benefits of your work, then you must produce it independently without the support and resources of the corporation.

Prices include shipping in Lower 48.

MEDA uMAG-02WB Handheld, battery-operated digital fluxgate magnetometer. Sensitivity: +/-0 - 20.00 - 200.0 - 2000 milliGauss F/S, DC-400 Hz (-3dB @ 400 Hz ref to DC). Analog output +/- 2.000 V F/S. Linearity .02% or better. Absolute accuracy +/- 0.5% or better, traceable to NIST. With 10 meter cable and transverse probe, 6 spare batteries in storage case, multiple-battery harness for up to 8 batteries (approximately 12 days continuous operation), analog output cable w/BNC (to oscilloscope input), manual, calibration certificate, transit case. In new condition. Current price from manufacturer is $900. Sell at $500.

WALKER SCIENTIFIC 3D1. Handheld, battery-operated digital fluxgate magnetometer. Sensitivity: +/-0 - 20.00 - 200.0 - 2000 milliGauss F/S, DC-100 Hz (-3dB @100 Hz ref to DC). Analog output +/- 2.000 V F/S. Linearity .02% or better. Absolute accuracy +/- 0.5% or better, traceable to NIST. With 6 foot cable and axial probe, carrying case. Almost-new condition, $350.

DEXSIL MAGNUM 310. Handheld, battery-operated, micropro-cessor based 3-axis digital induction milliGaussmeter. Auto-ranging; 0.04-9.96 milliGauss (+/- 2%), 10 - 99.6 milliGauss (+/- 5%), 100-996 milliGauss (+/- 5%), 1.00 - 10.0 Gauss (+/- 5%) for 60 Hz signals in 60 Hz mode. F/S accuracy in 3rd harmonic mode is +/- 5%. In braodband mode (40-310 Hz @ -3dB) accuracy is +/- 10%. Displays all three vector components plus resultant or resultant only. Has low battery indication and automatic shutoff. Fully self-contained. WIth carrying case, manual and calibration certificate. Used, very good condition; $250.

MERLYN & NIMUE 900. Handheld, battery-operated single axis digital induction milliGaussmeter. 4 ranges; +/- 0 - 20.00 - 200.0 - 2000 milliGauss - 20.00 Gauss F/S. +/- 2% all ranges except 20 Gauss (+/- 5%). -3dB 20 Hz - 1.5 KHz. Fully self-contained, w/carrying case. Used, excellent condition. $125

LEEDS & NORTHRUP SERVO RECORDER 136-304-304-304-00-00-00-L0088-L0088-L0088-6-BV-000. Three-channel servo recorder, modified for potential inputs. Can be internally adjusted from +/- 1 millivolt F/S to +/- 2V F/S. Set at +/- 1V F/S. Chart speed @ 60 Hz 2cm/hr or 2 cm/minute (at 50 Hz = 1.67 cm/min or 1.67 cm/hr). Internal line voltage selection for

100/120 V, 220 V or 240 V. Power burden: 27 VA. Power input; 3-wire IEC connector. (Uses standard IEC cords). With 2 sets spare pens, 2 boxes charts, a few spare parts, NEMA (USA) line cord, carrying case; Used, good condition; $150.

UNIVERSAL IEC LINE CORD SET. Each 6-foot line cord has a standard female 3-wire IEC connector at one end, and a male connector at the other; one of each from the following list:

Australia 3-pin w/ground male pin
Denmark 3-pin w/ground male pin
Europe 2-pin w/ground female & strap
India/South Africa 3-pin w/ground male pin
Israel 3-pin w/ground male pin
Italy 3-pin w/ground male pin
Switzerland 3-pin w/ground male pin
United Kingdom Fused 3-pin w/ground male pin
USA/NEC/Japan (100/120V) 3-pin w/ground male pin

One of each of the known electrical connections in the world; 9 cords in carrying case, NEW: $100

4777. Build or Buy BS-8 / PanAdapter

Hello All:
Here I go again, wanted, to either build or buy (used) a panadapter for my scope. I believe Kenwood's number is BS-8. If anyone knows how to simply build on, please, fill me in!!!! Thanks in advance, 73, Mike - WQ0N

...

Having looked at the specs of some microphone preamplifiers for
condendsor and electret microphones, I see that to reach down to
2 Hz, a (half-inch) microphone-preamplifer typically has an input
impedance of
32 GigaOhm, and a stray capacitance of 0.4 pF. And a noise voltage
of 2 microVolt.

These specifications are extreme compared to most quickly made
electronic equipment. I think it is unlikely that I could easily
build a preamplifier with such specifications.

With a 10 inch diameter microphone, maybe one could use a preamplifier
with 32/20/20 = 80 MegaOhm input resistance. That may be more realistic
for quick construction.

Regards, Anders

Back in the 70's, ham radio magazine had (as I recall) an article on a complete conversion of a tube receiver to solid state. More recently, there were commercial replacements for most if not all of the tubes in for the Collins S Line.

There are lots of reasons for making transistor equivalents. Some are to improve the reliability. Remember that as heat increases, reliability decreases.

>What do you guys think of all this? Should I stick with
>(understandable) vacuum tubes?

Stick with tubes, Bill.

As a first introductory project you might try to convert your
internet-adapter or modem to tubes.

OTOH, if all engineers working with tubes would have fully tried
to understand the Richardson equation, work functions et.c.,
there still would be no microelectronics.

Moritz

I have only 1 more of these to sell :

BRAND NEW, UNUSED, & IN-BOX : Portable Rechargeable Power Center :

Provides 12 vdc @ 4 amp (4 A.h.) and 3,6,&9 vdc @ 1 amp. Has pop-up carry handle,

Nylon shoulder strap, Built-in work light, Twin cigar (ciggarette) lighter outlets, Fuse

protected, Charge & Discharge status indicator LED's, and Auto DC charger

cord (recharges in your vehicle). Runs a lap-top computer for about 6

hrs., A cellular telephone for about 4 hrs (TALK) and 70 hrs. (STANDBY),

And who knows how long it will run an H.T. !!!

I HAVE ONE, (1), OF THESE TO SELL (Maybe more later.....MAYBE) $25.00 plus

actual shipping charges from IN. to you. E-mail me WITH YOUR ZIP-CODE

if interested ....

Thanks ! .... Roger N9PMC :-)

E-Mail Your Way To Riches!

Dear Friend,

We all know E-mail is here to stay. It's fun, easy and exciting! Would you be interested if we could show you a way to make well over $1,000 per week doing it?

This is not a joke. You may have seen many people trying to tell you that you can make money by joining this or that scheme! Guess what, you decide to go for it and then you get nothing but frustration and disappointment! We are here to take your frustration and disappointment into an Electrifying Adventure!

We have been marketing on-line for almost 2 years now! We have never spent one red penny on advertising and made nothing but profits. We can show you how to make money every day of the year. Many people may think this is untrue or it just can't be done. We are here to tell you that it is absolutely not true. The biggest mistake people make about marketing on-line is that they sit and wait for people to contact them. You will never make it if this is your approach and we'll tell you why. There are over 60 MILLION people on-line right now, and seven new people logging on every minute of the day world-wide and everyone is offering something. So how do you get a potential client or a new customer before your competition does? The answer is simply " Creative E-mailing" and it WORKS! I'll tell you why. You're taking your product, service or idea directly to the market instead of waiting for the market to come to you!

Here are a few testimonials we'd like to share with you (They're all 100% TRUE!):

Internet Communications, my wife and I owe you so much. We ordered your Creative E-mail System and within the first week we received over $1,150 in orders for my Internet Consulting business!
--Charles -- California

I have bought two so-called E-mail programs that cost me over $600.00 when I received them. They were extremely difficult to operate and it took me about two weeks to figure them out. Once I did, they were so time consuming it just wasn't worth my time. When I received your course it took me about four minutes to install and I was in business! Within the first 24 hours of my first E-mailing I received over $580.00 in sales over the phone. That first week I grossed over $2,000.00! I really can't believe how easy you made this, anyone can do it! Thanks!
--Dennis -- Illinios

Hello, I'm a divorced mother of two children. I wanted to thank you for helping me out. This was my first time buying anything on the Internet. I was skeptical at first but I figured I'd take a chance. This was the best chance I've ever took! My part-time business is now a full-time home-business, thanks to your

Creative E-mail System. I had to hire my two family members to help me out!
This is GREAT, thanks so much! I'd recommend this for anyone!
--Ellen -- Florida

You may have seen other people offering products "E-mail Programs, E-mail Addresses, Extractors, Etc." The vast majority of these products are very over-priced and very difficult to even use. None of them even supply you with current, up-to-date, FRESH & RESPONSIVE E-mail addresses! Our Creative E-mail System puts everything into one package to make your profits soar immediately! Even if you do not have a product or service to offer, we are going to give you over 500 how-to reports that you will have full reprint rights to! What makes our course different from anything else being offered anywhere is that we're dedicated to your success! We do not succeed unless you succeed! All of our E-mail Address Databases are created in house. We do not trade our databases with anyone because people are selling extremely bad lists on the Internet. Many of other people's databases are filled with duplicate addresses and many of them are undeliverable. We keep our own database so we know exactly what we have and we keep nothing but the best. There's no other way. We believe in producing high quality products that should be priced reasonably for your success! Read on to see the special bonuses you will receive.

******** SPECIAL 10 DAY BONUS ********

If you order within the next 10 days we will include:

1) 500 How-To Reports (You may resell these at any price)

2) Your Personal Complete Guide To The Internet -- This 175 page e-book covers every single aspect of the internet. You will never have to buy another internet book! When you complete this book, you will know more about the internet than 90% of the people online right now.

3) When you purchase our 8 MILLION SUPER responsive E-mail list we will include Mega-Mailer. It sends 250,000 E-mails per hour! All other orders will receive Pegasus Mail. It mails about 30,000 per hour.

Here's how to get the Creative E-Mail System:

All orders are delivered on CD-ROM or 100mb Zip Disk (Iomega).

============> E-Mail Databases <================

2 Million FRESH E-mail Addresses only $ 99.95
4 Million FRESH E-mail Addresses only $179.95
6 Million FRESH E-mail Addresses only $249.95
8 Million FRESH E-mail Addresses only $299.95

You will be sending your Marketing Letter to 2, 4, 6 or 8 MILLION People! To mail to 2 MILLION People by U.S. Mail at $.32 per stamp would cost $640,000.00, not including envelopes or paper! The price of 2 MILLION E-mail Addresses isn't even a fraction of the cost. And the great thing is that if you have 10 products, you can E-mail to your list as many times as you want to! Your profits will never stop soaring! Don't pay someone else to send your

advertisement out, do it yourself and save big money! The average cost right now to send your ad one time to ONE MILLION people is $1,400.00. You can send it 100 times to EIGHT MILLION people for only $299.95 and that includes Mega-Mailer that sends 250,000 per hour!

==========> Order Form <==========

Yes, Internet Communications Inc., I wish to take you up on your SPECIAL 10 DAY OFFER FOR YOUR CREATIVE E-MAIL SYSTEM, INCLUDING THE TWO SPECIAL BONUSES: "Complete Internet Guide Book" and "500 How-To-Reports". I understand I have to completely fill out the order form so you can fulfill my order.

4800. ATLANTA RADIO CLUB'S HAMFESTIVAL JUNE 21-22 1997

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-05 00:00:00 UTC
From: rychard@atl.mindspring.com
Message-ID: <5kjda9$i9@camel4.mindspring.com>
Source record: 94348

THE 69TH ANNUAL ATLANTA RADIO CLUB'S HAMFESTIVAL

The Atlanta Radio Club's Hamfestival on June 21-22,1997 is
the Southeast's premier hamfest.This hamfest is brought to you
by the Atlanta radio club,with the help of many of the local
radio clubs here in the metro atlanta area.This is our club's
69th annual hamfest,and with your attendance we hope it will be
our biggest and best to date.
This years event on June 21-22,1997 will be held at the
Atlanta City Hall East-Exhibition Center,675 Ponce de Leon Ave.This is
the same great site as last year's hamfest,which is near the downtown
area,and very easy to get to,and plenty of free parking.
On the days of the hamfest,we will be usings our clubs repeater
(W4DOC 146.82 Mhz minus 600Khz offset) on top of the Nations Bank for
talk-in.This repeater is used every Sunday night 8:00 pm for the
Atlanta Radio Club's net.If you are in the area your presence on the
net is welcomed.
For much more information about our Club and Hamfest plese check
out our web page at http://www.saf.com/arc.The club's BBS at
770-850-0546 has a lot of info also, or send email to dickb@akorn.net
our regular address is ATLANTA HAMFESTIVAL
P.O. BOX 942150,Atlanta Ga. 31141-2150
No matter what your interest in the radio hobbies are,you will find
you came to the right place.Amateur Radio,Shortwave radio,Scanners,
Satellite radio,Emergency radio,Marine radio,Military surplus
radios,etc.AM,FM,SSB,CW,PACKET,RTTY,SLOWSCAN,FAX,DX,ATV,AMTOR,EME,whatever
your interest this is the place to be.If your into building or
homebrewig equipment,radio or computer this is the place to find those
hard to find parts and gizmos.
The computer hobbies are doing better than ever and these interest
will be well covered at the Hamfest.
Buying,Selling,Trading,Swapping,Dealing,Bartering,Giving will all
be happening at the hamfest,probably some begging also.Whether your
coming with money to buy,a load of goods to sell,or just looking
around this is going to be a great hamfest.

The Atlanta Radio club has our regular meetings the first Thursday
of each month.These meetings are at 7:30 PM,located at the Georgia
Power Fedral Credit Union, 4900 Ashford-Dunwoody Rd.this is near the
I-285 loop on the north side of the city.
The Atlanta Radio Club is a non-profit organization wishing to
promote Amateur radio to all interested.
Our club president is Bill Bass W4LFC ph# 770-493-8438,his email
address is BillW4LFC@juno.com ,our vice-president is John Talipsky,Jr
KA4VQH ph#770-925-7110 his email address is johnka4vqh@juno.com ,our

club Secretary is Penn McClatchey K4PE ph#404-605-0742 his email is pmm@saf.com our Treasurer is Charles Golsen N4TZM ph#404-252-3303 his email address is cgolsen@atlanta.com ,our clubs activities manager is myself Richard Dean Young KR4IU ph#404-622-8433 my email address is rychard@atl.mindspring.com ,the opinions expressed are my own and are probably bias due to my love of the radio hobbies.
Hope to see you at the hamfest soon.

I would think that stepper motors driven from the same source would
work pretty well. You can either use two drivers driven with the same
timing or try wiring the motors in parallel and use one driver.

Source record: 94278

There's no such thing as 'decent coverage' with an indoor
antenna. At best, it's a compromise close to waving a white flag.

How about a tuner and open-wire feeder to a 40m half-wave dipole.

Just string/hang/drape the antenna through the apartment. I used
to have a dipole for 40m running from the far corner of the bedroom
half way down the wall, up to and across the ceiling, into a short
hallway, across the living room ceiling, then halfway down the far
corner. I worked QRP on 40m and worked many states. It was
fun. I expect if you are running a 100w radio, you might have better
luck. Don't forget that we are still close to the sunspot minimum
(supposedly on the rising side), so conditions on 10 and 15 will
not be expected to be very good. You should have fun with 20 and
40, though.

Of course, you have done the licensing 'thing', right?

If you don't know where you are going, you should have all the
docs on your equipment to prove ownership. You might check
with the ARRL and see what their latest words are regarding
amateur radio operations in any of the countries you might be
entering. Some may require the impounding of the equipment
until you show a valid license for that country.

Good luck and have a good time....

Why not go for a end fed long wire, might not be as efficient as other types
but it works and can be set up and taken down with ease, only problem it
needs to be long around 39 meters should be be fine for what you require.

ou will have to find a ATU that can be used with it. It is just a long
lenght of wire strung up between two points so it can be `hidden' in an
apartment set up quite easly.

(rec.radio.shortwave removed, since this is turning into a homebrew
thread!!)

Well, not meaning to nit-pick ;-) but H2 _is_ used in thyratrons. We
are using an EEV FX 2530 to gate a nanosecond flashlamp. I believ H2
gives a much shorter pulse than anything else. Then I actually have to
question the existence of "lithium anhydride"... Lithium Aluminum
Hydride, yes. Not that you'd want to get _that_ stuff into contact with
water!
Regards,
/hcb

Eimac type YC156. This is the same basic tube as a 4CX5000. It is a high mu triode with beam forming cathode and grid that provides the gain of a tetrode. Power gain is 15 db. It was designed for the medical industry and has a rating of 6500 volts at 4 amps (67 amps peak in pulse mode !) This tube will operate with full output to 110 Mc. No socket is necessary for this tube, it will mount in a 3 1/2 inch diameter clear hole, and the grid ring will bolt to the chassis. Height overall is 8".I have all data sheets. Tubes are used but emission is guaranteed for full output. $325 each.

to
>:meet Anders' needs.
>:
>
>I think Radio Shack still sells one of those

I imagine the PZM microphones utilize a sheet of
poly-vinylidene-difluoride?
And have a relatively low sensitivity?

Presumably the problems with preamplifier input impedance would be
similar to those of more normal electret microphones, and the noise
problems would be greater?

I couldnt find a radio shack in the telephone book. How would one contact
a radio shack office? Do they perhaps have an Email address or FAX
number?

4815. Apartment HF Antenna Question

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-06 00:00:00 UTC
From: wiley@acc-net.com
Message-ID: <5km5e5$25h@usenet85.supernews.com>
Source record: 94285

I am planning on possibly leaving the country soon, and am looking for any HF antenna designs which might be usable in an apartment. The details of what country I'll be in are still uncertain, but I'm looking for a design which might provide decent coverage of the 10, 20 & 40 meter bands (given the size constraints).

I'm not sure what would be best. One person I talked to mentioned something about a hairpin' antenna. I have no idea what that design is. So far, I've been lucky... I've been able to use dipoles and Yagi antennas. If I go into this apartment situation, I won't be so lucky. So, any ideas, suggestions, pictures or designs anyone might have would be appreciated.

Thanks and 73 de Bob, N8MMR

The SAD part is that hams not only DO NOT carry the ball in that part
of the reasons for the AMATEUR RADIO SERVICE (not hobby) to

even exist, that is to carry forward an ever-advancing state of the art, (Which does not mean supporting Japanese electronics firms).

SADDER STILL is the fact that if someone DOES try to start a discussion of radio qua radio, he/she is likely to be derided, and/or buried in trivia.

I've seen it several times.

Hi there,
I'd like to know if somebody out there ever tried to lock a TCXO on an atomic broadcasted frequency reference such as (US) WWV, (D) DCF 77 or (F) France-Inter.
More specifically, I'd like to know about the lock filter : cut-off, step size, etc...
The goal is to realize a highly stable reference oscillator for a linear 1291/1297 MHz repeater. I'd like something like a 10^-10 precision (long-term, but I am also interested in reducing short-term noise)

Since I don't receive the "rec.radio" groups, I'd greatly appreciate an email answer ! :)

Thanks a lot

4820. Info re MM5314 digital clock chip?

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-06 00:00:00 UTC
From: raateland@vyh.fi
Message-ID: <1997May6.183335@vyh.fi>
Source record: 94290

I'm waiting for a Whiterook Digital clock type CK-1 to arrive and I know I will need to modify it for 50 Hz operation instead of 60 Hz.

The clock uses an MM5314 chip, or so I'm told. National's Web pages have nothing on this chip and I've only got a pin-out. That may be enough, but if anybody happens to have a data sheet or other design information on the MM5314, I'd be interested to have a copy.

The clock has a backup circuit for when the line power is disconnected or failing. This works with a crystal oscillator and a divider circuit to produce 60 Hz replacing the US line frequency. The clock IC itself can be switched from 60 to 50 Hz operation by pulling a pin on the IC to ground or Vcc.

What I would like to find out is, whether switching the clock IC from 50 Hz back to 60 Hz operation disturbs the operation of the clock chip? I plan to switch the chip mode during a power failure at the same moment that the Xtal backup circuit kicks in.

If my plan flies, I would not need to replace the original 3,759 MHz Xtal with a specially made one, just add a little circuitry to do the mode switching.

Thanks for reading this.

Arjen-

It has been about 20 years since I built a clock from parts obtained at the local Radio Shack store. The plans were provided with the clock chip.

My clock still works, but I don't think I have any of the documentation. I don't recall if it has the MM5314 chip, but your comments ring a bell. For one thing, mine has a pin that changes from 60 to 50 Hz. It happens that the same pin also changes from 12 hour to 24 hour format, which is what I wanted. In order to use it with the local 60 Hz power, I found a scheme that used a TTL counter to ignore every 6th cycle. (I think it was a decade counter where the output from the divide-by-5 was connected to reset, or something like that.)

I also employed a scheme to use a color burst crystal (3.579545) retuned to 3.579540, to produce 60 Hz, and used a 9 volt diode-isolated battery to backup the power. When power fails, it doesn't miss a beat. However, it always is being driven by the crystal oscillator, so doesn't keep time as accurately as if it were always on the commercial 60 Hz power.

4825. W7ZOI GDM w. MFJ259

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-06 00:00:00 UTC
From: J M Noeding <la8ak@online.no>
Message-ID: <336FA441.1484@online.no>
Source record: 94295

See QST May 86, W7ZOI: "Beyond the dipper". My opinion is that this article
was not presented in the most effective way and it did not receive the interest
which it deserves. I have only found it mentioned in one other Ham-radio
magazine, the former YU-Amater magazine, where I could only understand the
circuits....hi (but they also had some translations of my articles...)

```
|----------|
RF-----------| | loop1 -----this part is not used with
MFJ259---
| |----gnd |
| |-------->|------|------DC to sensitive
| |---gnd | | DC amplifier
-------gnd---| | loop 2 10nF
|----------| |
---gnd
```

A few month ago I discovered the notes written by W7ZOI and made some
experiments with two probes. tests were carried out in the frequency range:
2-500MHz. It is obvious that it is a distinct advantage to use a continiously
variable signal generator, a digitital thumb wheel generator like Wavetek
model 3001 is not easy to use
Tom, LB8X reports that the W7ZOI circuit works for MFJ259 (see note*), the RF detector and amplifier is not
needed. This may even work much better than the optional GDM function for
the MFJ259.
It consists of very few parts, a pcb laminate (say 30x30mm) - used only to
mount and ground connections for RF input connection and a simple 1:1:1
ferrite transformer (10+10+10 turns on almost any small core may work)
Noe the phase relations on the output side.
With a hacksaw - cut of the copper foil in a 5mm broad segment from the end
cut this into three halves, and use them to support/solder the coils.
The two loops as connected in series will load the RF port very heavy and
RF signal drops, but as one coil is in tune with an LC circuit the balance is
disturbed and RF output reading increases.

*) MFJ has such frequency ranges: 1,4-8, 4-10, 10-26, 26-62, 62-113, ...MHz

Please excuse me for me not can speak English, please (Thank You!) - so please read W7ZOI's notes before requesting further technical explanation!

I agree. I use a dipole for 10 MHz and get good results on 40, 20 and 15.
It has tuned feeders and I use an ATU. Best DX has been to work the USA
with 2w (SSB & CW), but such contacts are rare. However contacts up to
1000 km or more are very easy and often solid with QRP.

unit77 wrote:
>
> WHY do you NEED an amp on 10 mtr?

If you've ever worked a DX pile-up on 10, you know why.

It's nice to work VKs on QRP phone -- I've done it from Texas -- but it doesn't happen very often and sometimes the "minimum power required to establish and maintain communications" is a kilowatt, even with a decent beam antenna.

If you're using an HTX-100 or a CB conversion, sometimes it's nice to get up to "normal" ham power levels, especially if you're mobile. That's when it would be nice to have a 10 M amp. Too bad it's so hard to get them for legitimate use in this country.

I bet you'd be surprised at the number of hams who've removed ILLEGAL CB "leen-yars" such as the Texas Star amps from CB service, and made them marginally legal by putting them on 10 or 15. You get to do this once a year.

4830. Groundfloor Apartment Antenna

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-06 00:00:00 UTC
From: jupiter@europa.com
Message-ID: <jupiter-ya023580000605972055320001@news.europa.com>
Source record: 94300
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.antenna

Saw other messages about apartment antennas, thought I would share this:

I worked my first BY (China) station back in the mid 80's on an apartment antenna.

It comprised of a hardware cloth (galv steel mesh) that covered the entire area underneath my futon, which was right against the floor. I surmise that the floor had a pad underneath the carpet which was on the concrete.

The hardware cloth had some copper wires soldered to it so that they radiated from the center of one side out to the circumference equally spaced.

That made up the rf ground. I had a seperate safety ground.

An MFJ tuner was mounted directly on the hardware cloth and directly attached to the meeting point of the copper wires. Do not use any length of ground wire from the tuner to the cloth. Even one foot has too much loss.

I then attached a heavy teflon insulated 12ga wire (they are all silver plated) from the antenna input of the tuner to the ceiling.

On the ceiling was a 3ftx3ft piece of hardware cloth similarly soldered with copper wires.

The ceiling part was tacked into the plaster.

The antenna worked on all bands except 160m where the extra coil burn up :)

I suppose its possible to build a dipole like this with the giant capacitive hats tacked to the opposing walls of your apartment; but I have never done this.

Remember, that radiation of rf depends only on the current flowing through a conductor (Maxwell's law). More than likely, a homebrew tuner optimized for extreme current would be much better than MFJ- but then it worked OK for me with only Drake TR-7.

Have fun, and be careful with that deadly emf :)

Rob.

ps. that capacitive hardware cloth ground was killer on all bands incl 160m with a wire up 100ft into a tall pine tree at my last QTH. At the legal limit, no induced rf on ground with just one safety ground and no ground

radials or stakes.

4831. Tubes vs. Transistors: Better Performance in Rcvrs??

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-06 00:00:00 UTC
From: jupiter@europa.com
Message-ID: <jupiter-ya023580000605972131530001@news.europa.com>

Cross-posted to: rec.radio.amateur.boatanchors,rec.radio.amateur.homebrew

Saw this thread in boatanchors and couldn't resist when I saw Mr. Newkirk slamming tube technology in receivers.

The real question that should be asked is:

Given the performance of designs published in the latest two ARRL Handbooks and even in the 1977 Solid State Design for Amateur Radio book; how can the ARRL with a straight face give favorable reviews to the latest Japanese transcievers with such mediocre basic receiver performance? I would be embarrassed.

When you look at IMD with preamp on, these $5000 units are years behind the state-of-the-art in basic receiver performance. I would bet any amount of money that in many multi-multi contest situations, Wes Hayward's 1977 DC receiver designs could receive signals that the so-called modern transceivers could not.

But back to tubes- Ulrich Rohde publised an article in QEX (April 1993, p. 11) where a tube receiver sported a +30dbm intercept. Clearly, there is great potential for high performance tube receivers, where uP/computer based features are not an issue; or for tube front-ends in some hybrid receiver. Who cares about memories and DSP in a contest situation where your front-end is being crushed??

One of my future projects is to implement an H-Mode mixer with nuvistors; and install it in my R4-C. I currently have an SD5000 module that plugs in to the first mixer, but the impedence conversion from tube to solid state adds too much loss.

Rob.

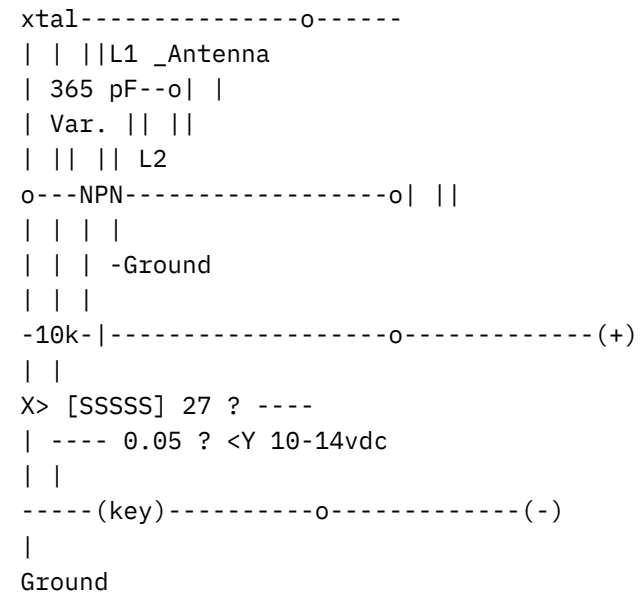
I found the plans to a 500mW transmitter on the "Homebrew QRP
is Gud 4 U" Page (http://brink.com/brink/QRP/) and, for the
life of me, I can't interpret a few symbols on the schematic. I
havent built anything yet, but I'd like to get into building
QRP stuff because it is a.) cheaper b.) gives me more experience
with electronics.

Anyhow the schematic reads, from positive power,

10-14 vdc power
10k ohm resistor
xtal (by the way, where can I get a 40 meter crystal?)
365 pF variable capacitor
loops (needs explaining)
antenna, grounded
?????? (unknown, two parallel lines, looks similar to capacitor, labeled "0.05") please
refer to as "Y"
ground
NPN transistor
?????? (unknown, rectangle w/ "s"s in it, labeled "27") <---please refer to as "X"
key
negative power

looks like:



ANY Help would be appreciated. THX for your time, sorry about crude
drawing/ explanation. Bear with me: Im new at this.

I had one of these. HAMCOMM works better. I think I still have the schematic around here somewhere. Basically, there is a TTL serial out line which you could probably connect to a line on your printer port. You would then have to cook up software that implements a UART, and is capable of decoding baudot, FEC, etc, whatever you want. This interface uses one of those EXAR modem chips (2211?) and is very sucepable to noise. I think you are better off with one of those op-amp demodulators and HAMCOMM. If you do that, then you can use JVFAX and get fax and a whole slew of other modes. It was worth $2 for the case, so I would start there and build something better.

Brad

4835. TM-V7A Software Coming from Kenwood

I spoke with Kenwood's Technical Representative today and he related that within a week or so - perhaps in time for the Dayton Hamfest, Kenwood will have a Windows 95 program that will allow file uploads and downloads from the TM-V7A. It will enable alpha numerics for and load the memories with frequency and PL tones. No other remote programmability is planned. The program is supposed to sell for $39.95 and use the data port & PG5A connector.

This will certainly take the pain out of loading memories - especially after a CPU reset!

I had email to/from the company that is actually doing the work on this project. I put a bug in their ear that since they had the interface to communicate with the V7, gee, wouldn't it be a great way to make a cheap remote base? A single card computer talking to the V7 and all you would have to do is plug in a control receiver... simple and cute.

Major hint. The control head is just that, a control head. Four wires (ground, power, data in and data out) are all that will be used. Someone want to figure out how to interface it? Or make new software other than the cloning software?

Rick

Looks good but I've never seen a real tube that got dimmer when you
tuned in a strong station!

Seriously, the only problem I see on a quick look is the heater
circuit of the 35W4. A real 35W4 (or 35Z5) has the tap far off center
to keep the pilot lamp voltage low. And why are there diodes
connected to all the heater pins? Was the B+ too low with only the
plate connected? If so, fixing the heater resistors may fix it.

So this is the equivalence of mounting an loudspeaker element on a small baffle. When the cone moves outwards, some air slips around the edge of the baffle to the opposite side of the baffle to the opposite side of the cone. This is known as an acoustics short circuit. At frequencies below and wavelengths above, where the total round trip distance is less than half a wavelength the frequency response drops rapidly. At such a small baffle, the frequency response starts to drop at several hundred Hertz, remembering that the wavelength at 100 Hz is 3.4 m. This applies to a loudspeaker element installed on a baffle and I do not see any reason why this would not apply to microphones as well.

To prevent the acoustic short circuit, loudspeakers are usually mounted in closed boxes. When a microphone is installed on a closed box, it actually measures the instantaneous pressure difference between the static pressure within the closed box and the instantaneous pressure in the sound field. To prevent blowing the membrane when the external static pressure varies (due to change of weather or change of altitude) some means to bleed off the static pressure difference must exist. This "leakage" will have a cut off frequency at some low frequency.

Before going too deeply into the electronic circuit of the electret microphone, the acoustic behavior should be checked.

Hello all.

I have a new 4-400A tube to install in my amplifier(Heathkit SB1000). However, the amplifier (and manuals!) are in Cyprus. I intend to try the new tube on a Heatherlite Explorer amplifier. I am not sure though of the procedure to follow. Do you just plug the tube and fire up? Or do you leave it on HV for some time and/or drive it initially with low power?

Any input appreciated.

Greetings,
Paris Andreou 5b4XF / G0WUT

Come, come. I was comparing the two and pointing out that solid-state technology is the appropriate technology for all but a very few mission-critical modern radio applications.

> The real question that should be asked is:
>
> Given the performance of designs published in the latest two ARRL Handbooks

The way I see it, the real question that should be asked is:

Why do observers continue to mistake the performance of particular implementations of a technology with the performance possible with the technology?

(A second question is why an adherents to a particular technology becomes sufficiently emotional to ascribe the verb "slamming" to the act of comparing another technology to a pet technology when the pet technology happens to finish second best. ;-D)

Of *course* particular implementations of solid-state technology, especially those designed to cost for consumers, may not exemplify the best that can be done for mission-critical work. The receiver mentioned next--

> But back to tubes- Ulrich Rohde publised an article in QEX (April 1993, p.
> 11) where a tube receiver sported a +30dbm intercept. Clearly, there is
> great potential for high performance tube receivers, where uP/computer
> based features are not an issue; or for tube front-ends in some hybrid
> receiver. Who cares about memories and DSP in a contest situation where
> your front-end is being crushed??

--is an example of this.

But take a closer look, please. I've listened to the BBC and amateur signals on one of those receivers--a Rohde and Schwarz EK-07D. Yes, it had an excellent front end. It was also so heavy that I had to have two neighbors help me lift it up our stairs. Its heterodyne detection ability was poor compared to our modern "product detector" radios--there was a lot of distortion--and the appropriate selectivity choice in that particular implementation was a bit too round for SSB. (Apparently an optional SSB adapter was available that processed signal from the radio's second IF output [300 kHz] with better selectivity and good "product" detection. And revised IF-amp modules were apparently available later in the EK-07D's life to improve on the inboard selectivity.) *And* it drew something like 140 W from the ac mains. But, as a superb work of industrial art, an EK-07D is a privilege to use.

Of course, I've been describing only one particular implementation of tube technology. But I reiterate what I said in the boatanchors group: In all but a very few applications, thermionic technology is not the appropriate technology when you need the best modern radio performance possible. I can't think of a single consumer-oriented radio-reception application, including amateur radio contesting, in which solid-state technology is not the appropriate technology. (That manufacturers designing to cost--especially manufacturers who market incremental modifications of existing implementations in differently shaped enclosures, with different user interfaces, as "new" to get consumers to re-buy--might produce widgets that don't achieve what's possible with the technology isn't surprising or unusual. Most vacuum-tube gear produced for radio-amateur use represented what was possible in tube technology just as poorly.)

Yes, it's possible that you can make a better vacuum-tube front end than the solid-state front end in a consumer-intended radio. But not if the solid-state front end to which you compare it represents the best that's being achieved for military and professional communication in 1997.

Regards,

David Newkirk, W9VES

:The way I see it, the real question that should be asked is:
:
:Why do observers continue to mistake the performance of particular
:implementations of a technology with the performance possible with the
:technology?

They are not "mistaking" they are "lamenting", since they are paying $3000 to $5000 for it! Duh. If I can build a homebrew radio for a couple hundred bucks that outperforms those with stratospheric prices, I'd say thats reason enough for concern.

I was going to buy an new Icom 775 a year ago, but I just couldn't do it, knowing I was supporting mediocrity in receiver design. If I was going on DXpeditions, I would surely buy a new compact transceiver, but in my case it made absolutely no sense.

:
:(A second question is why an adherents to a particular technology becomes
:sufficiently emotional to ascribe the verb "slamming" to the act of
:comparing another technology to a pet technology when the pet technology
:happens to finish second best. ;-D)

Actually, I am an adherent to a particlular level of quality- one that I haven't seen in a long time. Here all my receiver design is done with solid state. I really need to go out and get those nuvistors though. I do have a tube audio amp that I built from scratch, and my old Drake gear, that I am continually trying to improve by adding DMOS and other crap, and then putting it back into its original state.

:
:Of course, I've been describing only one particular implementation of tube
:technology. But I reiterate what I said in the boatanchors group: In all
:but a very few applications, thermionic technology is not the appropriate
:technology when you need the best modern radio performance possible.

An opinion. But since no-one except linear amp manufacturers do much with tubes anymore, its an opinion likely to stand forever in the minds of most.

:can't think of a single consumer-oriented radio-reception application,
:including amateur radio contesting, in which solid-state technology is not
:the appropriate technology. (That manufacturers designing to
:cost--especially manufacturers who market incremental modifications of
:existing implementations in differently shaped enclosures, with different
:user interfaces, as "new" to get consumers to re-buy--might produce widgets
:that don't achieve what's possible with the technology isn't surprising or

:unusual. Most vacuum-tube gear produced for radio-amateur use represented
:what was possible in tube technology just as poorly.)
:
:Yes, it's possible that you can make a better vacuum-tube front end than
:the solid-state front end in a consumer-intended radio. But not if the
:solid-state front end to which you compare it represents the best that's
:being achieved for military and professional communication in 1997.

I can concur with alot of this. However, what worries me about the state of commercial ham equipment today, is that it is so co-dependent (one of those psychobable words implying pathology) with the "dumbing-down" of the amateur population. Nowadays there is little reason for alot of people to really learn much of anything about electronics, and I'm not talking about memorization.

Finally, thermionic technology may indeed end up the RF technology of the future. I read an article where an IC manufacturer was working on integrated circuits using microscopic vacuum tubes with field emission cathodes. (because the geometries are so small, electric fields are high enough to strip electrons off the cathode at room temp). Because there are worried about secondary carriers, and electron transit time is so fast, these may indeed end up the fastest IC active devices ever produced.

This is fun. My account may expire at the end of the week, as I am considering going to ISP where articles don't have a 24hr lag time to cache, so please don't email responses.

Thanks, Rob.

Hi
I made a similar comment on the local repeater here in phoenix.
the topic was no-code vs. know-code.
except adding to the "number" what have they done to promote
ham radio. even the novice 20 years ago did his part.
built kits , learned electronics,and code.
now the newbies want it all for free.

4850. earn FREE digital display

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-07 00:00:00 UTC
From: Neil Heckt <neil@aade.com>
Message-ID: <3370F4FF.37C5@aade.com>
Source record: 94223

Many customers have requested a version of my Digital Frequency Display
(see May QST or web site below) for use to upgrade older equipment with
analog dials to digital dials.

The type of equipment which would use this consist of a crystal
controlled band switched converter (first LO) in front of a tunable IF.

Noteable examples (which I already know how to do) are the Collins
S line, the FT101 and TS-520.

I have developed a version that can measure up to three frequencies
and compute and display the RF frequency. The maximum limit on
any of the three frequencies is 50MHz.

The unit measures the crystal frequency, the tunable VFO frequency and,
optionally, the BFO frequency. IT then computes the RF frequency.
If the BFO frequency is available it will compute the actual carrier
frequency of SSB signals or the zero beat carrier frequency of CW
signals. As a function of the BFO frequency it will display the mode
USB/LSB/CW or AM.

What I need is people with older equipment that falls into the above
catagory who are willing to supply some initial information necessary
to design the electrical interface and then engineer the modifications
necessary to the unit to bring out the signals.

The initial information consists of:
1) the schematic and hopefully block diagram of their unit
2) the p-p voltage levels of the crystal, VFO and BFO signals
3) the main IF frequency
4) the frequencies of the crystals, VFO and BFO.

Togather we would plan and execute the modifications necessary to
bring out the signals to connectors. For example the FT101 signals
are tapped at PCB connectors and routed to spare pins on the auxillary
socket on the rear of the unit thru RG174 cable. The Collins S line
has these signals on the rear panel at RCA jacks.

If possible, power between 8 and 18volts at 20ma. or less should
also be brought out of the unit. In some cases it may be possible
to bring out a filament AC voltage which I can rectify.

You would then have to write the modification instructions and if
possible photograph them. I can use photographic prints or video
tape from your camcorder. (I have a flat bed scanner and a snappy
video capture unit).

In return for your effort you will receive one of the display modules
and credit for the modification instructions.

If your interested give me a call or e-mail me as shown below.

Thanks

: in series so that one is forward while the other is reverse biased, it
: will clamp at 1.9 volts. That would be excellent for the task.......sq

I'd like to comment on this and some other things I've seen in this thread...

First, low voltage Zeners have very gradual turnon. You are literally better off with a stack of forward-biased silicon diodes than a zener, up to about 6 volts. For really low-voltage zeners, below 3 volts, the effect is extreme. You might want to think of them as "nonlinear resistors". Of course, this is not at all the case with integrated-circuit shunt references. You can get "programmable zeners" which have very sharp turnons, though at the expense of some microamps of standing current below the turnon.

Next: in a clamp circuit that protected a line on which I did not want intermodulation effects, I'd for sure use low capacitance diodes. In fact, look for ones which have relatively stable capacitance with reverse voltage. I believe some of the PIN diodes are quite good in this respect.

I have to provide for ESD protection in the circuits I design, which must also be extremely low distortion for signals from the microvolt region up to in excess of 10 volts. What I've found to work very well is a signal diode from the signal line to a positive clamp voltage and another to a symmetrical negative clamp voltage. Generally I use dual diodes in an SMT package, which about guarantees them to be well matched. As the input voltage changes, the capacitance of one goes up and of the other goes down. The result, to a first order, is a very tiny capacitance change, probably in the less-than-0.01pF/volt range. I use +/-24 volts as clamp voltages for my circuits, but for a mosfet input would instead use something like +/-5 volts. You can get that from zener diodes, or even from a resistive voltage divider! If you put enough bypass capacitance from that node to ground, ESD events would cause insignificant voltage change on those nodes. Negative voltage a problem?? Well, you only need microamps to bias that node.

I hope my experience in this area are useful to others.

>
> I thought the carrier did not change but the amplitude of the sidebands
> changed, can someone shed some light?
>
> 73, Tim, ka8ddz

Well, you're right about the 100% modulation putting you "off the air",
in that there are swings in carrier (RF output) from ZERO to MAXIMUM
power, but without the swings TO zero power and back again to whatever
max power level there would be no power to pull/push your SPEAKER cone
from zero excitation or travel to maximum stroke to pump modulated air
pulsations out toward you (i.e., audio).
If you are looking at a 760 KHZ sine wave without modulation on it you
may be sampling too narrow a width to see the modulation or the
transmitter is not broadcasting any audio at the point you're viewing on
the waveform.
When I use a spectrum analyser (a swept receiver with output to scope
instead of speaker) to view RF signals, an AM station produces a
waveform dancing up and down on the screen in relation to the
modulation, and the FM stations really look funny, with a FIXED height
or amplitude display that slides back and forth SIDEWAYS (i.e., in
frequency) as the audio modulates the carrier.
Viewed on a scope with the proper response, the AM carrier is indeed, in
your instance, a 760 KHZ sine wave with all sorts of "squiggles" ON the
sine wave, complicating (modulating) it, and the higher the AM
modulation percentage, the more the 760 KHZ "sine wave" is disrupted
(modulated) by the lower frequency audio.
Viewing an FM carrier is also interesting, the modulation appears only
in the effect of the sine wave "springing" back and forth in width
(frequency) on the screen, very much like a slinky toy spring expanding
and compressing at an audio rate.

Sorry for the non-engineering response.

Source record: 94157

>Has anyone ever tried using a speaker with whizzer cone as a mike? You
>should get great low freq response.
>

Loudspeakers and earphones are sometimes used as makeshift microphones.
A 10 inch speaker (with a baffle) gives a similar output at 70 Hz as
a normal microphone. But the frequency response of the loudspeaker is
very unflat, and quickly drops off at lower frequencies.

It is very easy to interface to loudspeakers because of the low
impedance.

Possibly some earphones are better suited than a 10 inch loudspekaer.

Regards, Anders

>frequency at some low frequency.
>

True. In the case of cheap electret microphones, the closed box
is the small aluminium tube housing the internals.

The venting seems to be around the edge of the small circular pertinax at
the bottom of the tube.

This presumably can be sealed with an application of Loctite Multibond.

Alternatively, the microphone can be mounted inside a metal tube which
can be sealed behind the microphone. Still some venting is necessary
for safety reasons. Perhaps a small stopcock, in the form of a screw in
a hole?

Regards, Anders

4864. QRP (my first such homebrew) Xmtr chokes 2 minues after powerup

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-08 00:00:00 UTC
From: Douglas Wielfaert <marcy@vic.com>
Message-ID: <33728973.6FE8@vic.com>
Source record: 94159

Built the VXO controlled CW xmtr in ARRL QRP classics p 59 (1990 ARRL handbook c30 p.43). (30 meter version) I get a clean signal when I first turn the rig on (testing into a dummy load) I do hear a background oscillation in a nearby receiver even when the key is up though. The sig soungs good for a minute then gets very "Clicky" until it dies. The grounded base amplifier transistor (a 2N2222A) gets very warm to the touch. I have carefully checked the component tolerances including the transistors and everything looks O.K. Prety sure the bifilar toroids are wound in correct phase, but you never know. The specs call for a ground plane on the component side of the board. I did not do that. The crystal is 32pf from Peterson Radio. Oh... I am using 2SC2092s amplifiers instead of MRF 472s or MRF476s as called for.

Anyone have any ideas?

Doug Wielfaert

The Audio Engineering Society will hold its 14th International Conference entitled "internetaudio.aes.org" in Seattle, June 13 - 15, 1997. This conference will examine the technology shift toward computer-based, networked environments and its impact on the audio and
multimedia industries. This technical conference will feature presentations and demonstrations,
discussion and interaction to chart the future of the internet audio industry.

The 14th International Conference is chaired by three internet audio authorities: David Johnson
(New Media Designs, Inc.), Aurika Hays (Progressive Networks) and Ken Pohlmann (University of
Miami). The full three-day program will include ten technical Symposia and nine Discovery sessions, featuring more than 50 invited presenters, each an industry expert. Scheduled topics
include: open platform audio standards, audio policy and delivery, music and radio distribution
over packet networks, server push technology, point-to-point audio, workstations and editing
systems, online content development, perceptual coding for computer environments, binaural and
multichannel listening environments, virtual 3D audio, simultaneous multi-location recording,
internet copyright and the economics of internet commerce.

4869. Re: AM, why handbook shows carrier changing?

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-08 00:00:00 UTC
From: geotek@comwerx.net
Message-ID: <5ktbdm$6el@news2.zippo.com>
Source record: 94164

AM modulation is just that, Amplitude Modulation. The amplitude of
the carrier is changed in proportion to the applied audio. At 100%
modulation the carrier power does approach zero, but only on the
negative peaks of the siganl. The reason you were not seeing this or
the AM radio, is that you did not have your scope synced to the
envelope. Try the same experiment again, this time sync your scope to
the detected audio and observe the carrier.

I've bought an used PM 6669 counter without the HF input option (fmax 1,1 GHz) installed (and without the manual and the schematic).

I'd like to add an internal prescaler but don't know where to connect it to the counter circuit.

Any ideas?

Peter

Any good hardware store should have these.
the model for phone wire is the Arrow T-18
the model for thin coax(rg58/59) is the Arrow T-25
they make other models for thicker cables-the T-75 comes to mind

Any of the above will run around $25.00 or so(less in a GOOD store).
They are constructed very well, and will last almost forever.

4880. AM, why handbook shows carrier changing?

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-08 00:00:00 UTC
From: hynde@flash.net.no-spam
Message-ID: <33722027.5E75@flash.net.no-spam>
Source record: 94242

While trying to understand what is REALLY happening with AM I of course refered to the handbook. All the examples I've found show a modulated AM carrier with what appears to be a sine wave changing in amplitude with audio. I have a problem with this, if it's true when you hit 100% modulation YOUR OFF THE AIR.

What are they looking at that shows the carrier changing with audio?

When I look at a local radio station by using the front end of a crystal set and coupling it to a scope I see an nice sine wave at 760KHz and it AINT MOVIN!!

I thought the carrier did not change but the amplitude of the sidebands changed, can someone shed some light?

The solid-state focal planes for NASA's billion dollar Advanced X-ray Astrophysics Facility are protected by this scheme. The diodes are ordinary BAV99's, but they have gone through a fancy R&QA process to get the price up to NASA standard.

hynde@flash.net.no-spam wrote:

>What are they looking at that shows the carrier changing with audio?

The total output voltage of the modulated stage

>I thought the carrier did not change

It doesn't; that why you see a constant amplitude when you use a tight filter on the carrier. The carrier is on one frequency, one sideband is on a different, lower frequency, and the other sideband is on a different, higher frequency. The difference in frequency between the carrier and the sidebands is equal to the modulating frequency.

> but the amplitude of the sidebands changed

Right. When the amplitude of the two sideband voltages are exactly equal to the carrier voltage and also exactly out of phase with the carrier voltage the total voltage is zero. You'll recall that each sideband voltage (at 100% modulation) is half of the carrier voltage. That means the power in each sideband is 1/4 the carrier power. A station transmitting 1000 Watts carrier that is being modulated 100% has two 250 Watt sidebands also. All the information is being carried in a single one of the two sidebands. The other sideband doesn't add anything but a signal-to-noise improvement. All the carrier does is allow the use of simple diode demodulators. Which is why operating on AM is stupid for communicators: it takes twice the bandwidth to deliver a signal to noise ratio that's 5 db worse.

With amplitude modulation the carrier power level stays the same all the time--at least in theory--while total system power varies from zero (at 100% negative modulation) to four times the carrier power (at 100% positive modulation). But with FM the carrier level is always changing and at certain combinations of modulating frequency and frequency deviation the carrier is completely suppressed even though the total output power of the carrier and all the sidebands never changes.

Lots of people can't get a grasp on what's happening because they see the total voltage go to zero. But your experiment with the crystal filter has given you the ability to confirm the consistent level of the carrier.

I don't know the details of the Gonset, but you might post the basic frequency of the crystals (8 mhz, 6 mhz, whatever) so we can peruse our junkboxes for you.
6 Meter AM activity was abysmally low back in the mid to late 1970's when I became a 6 meter enthusiast, and 6 was the lowest DX frequency for Technician licensees back then, and they constituted the majority of the contacts I conversed with. 10 Meter SSB is now the DX band of choice for many if not most Techs and I think this has impacted 6 meter activity.
SSB had become the dominant mode by the mid- 70's and I eventually succumbed to 6 Meter SSB by building a transverter for my HF rig and eventually converted an old SSB CB rig directly to 6 meters.
There are probably a few 6M AM nets still in existence, especially in the Midwest, and when the band gets really hot there are occasionally some AM'ers that come out of the woodwork. But I think you'll find they are quite few and far between.

---

bit bucket /n./

1. The universal data sink (originally, the mythical receptacle
used to catch bits when they fall off the end of a register
during a shift instruction). Discarded, lost, or destroyed data
is said to have `gone to the bit bucket'. On Unix, often used
for /dev/null. Sometimes amplified as `the Great Bit Bucket in
the Sky'.

2. The place where all lost mail and news messages eventually go.
The selection is performed according to Finagle's Law;
important mail is much more likely to end up in the bit bucket
than junk mail, which has an almost 100% probability of getting
delivered. Routing to the bit bucket is automatically performed
by mail-transfer agents, news systems, and the lower layers of
the network.

3. The ideal location for all unwanted mail responses: "Flames
about this article to the bit bucket." Such a request is
guaranteed to overflow one's mailbox with flames.

4. Excuse for all mail that has not been sent. "I mailed you those figures last week; they must have landed in the bit bucket." Compare black hole.

This term is used purely in jest. It is based on the fanciful notion that bits are objects that are not destroyed but only misplaced. This appears to have been a mutation of an earlier term `bit box', about which the same legend was current; old-time hackers also report that trainees used to be told that when the CPU stored bits into memory it was actually pulling them `out of the bit box'. See also chad box.

Another variant of this legend has it that, as a consequence of the `parity preservation law', the number of 1 bits that go to the bit bucket must equal the number of 0 bits. Any imbalance results in bits filling up the bit bucket. A qualified computer technician can empty a full bit bucket as part of scheduled maintenance.

Response:

1. The carrier level is very much changing because it is sum and difference of the carrier + modulation. A typical scope will _not_ show this as it does not do a _spectrum_ analysis. At 100% modulation, the carrier goes to zero and all the power exists in the sidebands.

2. Above 100% _negative_ peak modulation, the carrier is indeed cut-off. This is what causes splatter because cut-off is a form of "rectangular" wave with many harmonics ...extending beyond normal voice frequencies. (Note: it is quite possible to achieve >100% positive

peak modulation for more punch; much depends on the RF amplifier, modulator and audio negative peak pre-processing).

3. To really understand what is happening, it takes understanding of Fourier transforms and analyses. There are many written sources of such theory. ARRL could do better by showing some typical scope spectrum analyses beyond the very simplistic representations. This would better illustrate the matter for "inquiring minds".

>Does anyone here know a source on electret microphone capsules with
>no internal FET. Alternatively a low noise low frequency electret
>capsule?

Sennheisers industrial electret capsules have connections so that
you can use them without the internal FET, or you can couple the
internal FET into your circuit in a variety of ways, which gives many
options.

You can use your own FET, if you find a lower noise one, than the
internal.

Can anyone recommend a low noise N-channel JFET?
I cannot find noise data on FETs..

I cannot find noise data on commonly available FETs.

Can anyone recommend a commonly available N-channel JFET as lownoise?

The signal is in the microVolt range, the FET is used as a source-follower, the current can be selected between 0.1 and 2 mA, whatever suits the transistor best. The source-drain voltage is expected to be around 4.5 V. The frequency range is audio, or subaudio. DC-160 Hz. (not kiloHertz)

Some time ago on here there was an article giving details of a site for
the vendor of these kits. I have since had a hard disk wiped by a faulty
motherboard, so would appreciate details.

: a hole?

Perhaps a (relatively long) capillary tube? You can draw extremely fine
capillary tubes from glass tubing. Just how low a frequency do you
need to get to, anyway? Also, it would be good to consider that
the noise of the amplifier will be going up at low frequencies
because the source impedance of the capacitor will be getting quite
high...a big advantage to using larger diameter microphones. Perhaps
a 2.5cm diameter?? We had some B&K 'one-inch' capacitor mic capsules
around here for a while.

> All the examples I've found show a modulated AM
>carrier with what appears to be a sine wave changing in amplitude with
>audio. I have a problem with this, if it's true when you hit 100%
>modulation YOUR OFF THE AIR.

This is exactly what happens. But you're only "off the air" at the
negative peaks of the modulating waveform. (at the positive peaks,
you're actually transmitting *twice* the power you'd have with no
modulation at all)

>What are they looking at that shows the carrier changing with audio?

What you see in the Handbook should be what you'd see if you hooked an
oscilloscope across your coax. (if you actually try this, hook some
kind of antenna to the 'scope's input instead; hooking it directly to
the coax is likely to burn something out)

Set your scope's horizontal sweep to a rate appropriate for *audio*
(not RF). You might first hook the scope to an audio generator set to
about 1KHz, and set up the scope to show that sinewave properly.
Then, hook up an antenna near your transmitting antenna. Don't adjust
the sweep controls on the scope. (you probably will have to adjust
the *vertical* attenuator.)

>When I look at a local radio station by using the front end of a crystal
>set and coupling it to a scope I see an nice sine wave at 760KHz and it
>AINT MOVIN!!

This is probably because you've got the horizontal sweep rate on the
scope set too high. Set it to a slower sweep rate (as I described
above) and I think you'll see something closer to what's in the book.

>I thought the carrier did not change but the amplitude of the sidebands
>changed, can someone shed some light?

Not really true. The whole idea is to use the audio to change the
strength of the carrier. On *average* the carrier stays put, but
during one cycle of the audio its strength goes up and down.

The result of this process are the sidebands, which do change in
amplitude and frequency with the audio.

4895. 13.5V 15 Amp Power Supply?

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-09 00:00:00 UTC
From: aco@almworks.com
Message-ID: <3372bbf0.38333385@news.erols.com>
Source record: 94169

Hello Everyone,

I am very poor so I would like to use my Mobile 2 Meter Rig in my house, rather than buy a "real" base rig.

I am very poor (remember?) so I would like to build my own power supply for the affore mentioned rig, a Kenwood TM-241A.

The Specifications page of the manual says that it operates 13.8V nominal +- 15% (11.7 - 15.8V) at has a current draw of "Less than 11 A" during "Transient Mode" which I assume means "when transmitting".

So the question I have is... Is it feasable to build a 120VAC -> 13.8V, 15A DC power supply? I have seen plans for 1A, 3A, 5A, and such in the ARRL handbook, QST, and a couple other places. But nobody makes high amperage supplies.

Does the cost of the transformers make it not worth building one? Is there some other reason? Does anyone have or have a source for plans for a medium-high current power supply?

I think that's enough questions for today. Thanks in advance.

Sounds like an automagically controlled regenerative detector.

But the problem here is detecting an oscillator that isn't actually oscillating, unless a very small amount of oscillation is acceptable. In that case, you need a sensitive RF detector coupled with some form of an AGC controlled LC oscillator. Correction - make that loop gain controlled.

GE did this way back in the early 60s. They called the units TIMs, Thermally Integrated Modules. Tiny tiny vacuum tubes combined in a single package to form the equivalent of a SSI IC. The intended market was space applications and highly radioactive environments where solid state couldn't survive. But solid state development so outstripped TIMs that they quickly disappeared.

4900. Help TEN TEC Active antenna kit

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-09 00:00:00 UTC
From: Zamphir <Look@bottom.com>
Message-ID: <3373DBB8.250F@bottom.com>
Source record: 94174
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.shortwave

I just got through building one of these little kit boards.
I had no problems with the construction. I housed it in a metal
case and use a 9 volt battery for the power source. The problem
is I can't figure out if it's working or not. I've hooked it to
my Sony Pro-80 and it doesn't show any improvement over the stock
telescopic antenna. The gain control doesn't seem to have any
effect at all (The manual says it should have a very noticable
effect) I checked the voltage on the drain of the dual gate =

MOSFET and it varies with the gain control from 8.5 volts to
9.7 volts. This drain feeds into a .01 ceramic capacitor then
directly to the receiver hook-up point on the circuit board.
Has anyone else out there tried this kit? If so, what are your
results with it. Maybe I'm expecting too much from it, but would
like to see it make some difference.

Ricky

At the moment I intend to use 1.5 cm diameter electret capsules. I havent
seen larger electret capsules.

I intend to use a Burr Brown OPA121KP DIFET opamp. With an input
resistance better than 1 TeraOhm, and a noise around 6 nanoVolt per
squareroot Hz, it is difficult to beat.

>Doug Wielfaert
>WB8PAD

Doug: Amazin! A couple of years ago I built two of these rigs, one
for 20 and one for 30. Both worked great from the very first try.
Today I was going to post a question about the history of this
circuit. (See my other posting).

A couple of observations:

-- You are supposed to hear the oscillator during key up. this design
keeps it running all the time to prevent unwanted frequency shifting.

-- As I recall the driver transistor does get hot, but it should not
get too hot to touch.

-- Make sure your power supply is adequate. It may be that even with
this little rig, you are pulling more amps than your supply can
provide. If you are using a battery, try getting a bigger one, or
putting a few smaller ones in parrallell.

-- Also, make sure your antenna is providing a proper load. Try
running the rig (briefly) into a 2 Watt 51 ohm resistor. See if you
notice a big increase in monitored signal strength when you key down.

-- I wouldn't worry about not having done the ground-plane thing. I
used this technique with mine but I'm not sure it was absolutely
necessary.

Keep us posted. I had great luck with this rig. My first CQ was answered by a statio in Poland! Didn't even have the rig in the box yet!

Back in the 70's QST ran an article about solid state tube replacements.
Howard Sartori W5DI(?) made replacements for the Drake line. He marketed them
under "Sartori Communications" business. I put his units in my R4C and to this
day the rig still outperforms my TS830S receiver section. I run the Drake's
for serious weak signal DXing. My T4X has several of his units in it. Except
for the driver and tubes in the antenna relay change over filiment string I
have the replacements. His replacement for the change over relay never could
get working right. It always locked up the rig in transmit. Since I couldn't

get this end working, I couldn't run his repalcements in the rest of the tubes in the filament >chain. However I do get full output and great stability with the replacements.

The few crystals I have here are 8 mhz range. Gonset apparently used a 6X multiplier, at least for the 6M rigs. At 50.4 this would mean 8400 Khz crystals would do. These are FT-243 packages.

I have quite a few responses regarding these crystals. Apparently there is a good supply available. Anyone needing any can contact me and I'll provide the reference I have as to where to buy them.

Thanks to all who have responded.

>I aim at 2 Hz.

I did not realize that you needed to go down that far, what is the
required upper frequency range ?

Long time ago there were condenser microphones in which the variable
capacitance of the microphone capsule formed part of an oscillator
tank circuit. The output was a frequency modulated carrier and the
audio was recovered with a frequency discriminator.

The early radiosondes (at least those made by Vaisala) used capacitive
pressure and humidity sensors that directly modulated the transmitter
frequency.

I have not heard if anybody has tried this with an electret capsule,
but if it works, the electric (but not acoustic) frequency range would
extend down to zero.

Have you looked at different kind of pressure sensors, if you must go
this low ?

Negative. The carrier amplitude does not vary.

What you see on an oscilloscope display is the time domain vector sum of the carrier and the sidebands. *That* can vary with modulation, but the carrier does not. If you observe the signal on a spectrum analyzer, you see that the carrier remains constant while the sidebands vary with modulation.

To see the display shown in the Handbook, you have to slow the oscilloscope sweep down to an audio rate. The vector sum of the carrier and sidebands does vary at an

audio rate. That's

y = A*cos(wt) + (a/2) *cos((w+p)+phi) + (a/2)*cos(w-p)-phi)

The first term is the carrier, the second is the upper sideband, and the third is the lower sideband. 'A' is the carrier amplitude, and it is a fixed constant. 'a' is the modulation amplitude, and it varies with the audio applied. Note that half the available modulating energy goes into each sideband. The cosine terms are the vector phases of the various signal components.

Source record: 94189

Howdy,
I've been using the PNP Blue to get art into resist on the board,
but, even with the small, simple boards I make, I always need a little
touchup, both before and after etching.

My complaints about PNP:

1. the heat fusion to the board step seems pretty touchy, involving a
heat/cool/inspect repeat-as-needed dance.

2. the chronic touchup needed, caused by non uniform adhesion of film to
board, caused by 1 (above)?

3. I usually see some sort of parallel lines running thru all the
remaining copper... they're not deep enough to cause trouble,
but they're not pretty, either.

4. I think DIP spacing is about as small as is possible (ok so far,
but it might be nice to have a little more resolution ready).

I've tried photo transparencies and photo resist board, but the photo
stuff goes out of house, takes some time, costs some money.What are other
options for getting small boards from artwork to copper? Thanks.

Yeah. As noted by other posters, exceeding 100% negative modulation
causes huge amounts of distortion. But 100% peaks are relatively rare
in the complex voice envelope. So most of the time you can run less carrier
without having the sideband amplitudes exceed 100% modulation. This
saves electricity since you don't have to waste it on an excessively strong
carrier.

To do this, you modulate the RF drive to the PA as well as modulating the PA
in the conventional manner. You arrange phasing so that when regular modulation
would drive the carrier beyond 100% modulation, drive increases to prevent that,
and when there is little modulation, drive decreases so that there is also little
carrier.

4918. VERTICAL ANTENNAS

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-09 00:00:00 UTC
From: jorgegc@mundivia.es
Message-ID: <337795ea.339286@noticias.mundivia.es>
Source record: 94192
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew

Hello Friends !

My name is Francisco and first of all let me thank you for reading this message.
I have some questions and doubts about HF antennas, so if you can help please send me a message.
My antenna instalation nowdays is a windom antenna that I made myself with a 1:6 balum, which is 41 metres long and it works ok on 80,40,20,17,12 & 10 metres. It is at 4 metres over the roof of my 14 floors building. I also own a commercial vertical for WARC but I donnot know it's name. It has a first part of aluminium for 12m, after that a coil and another part of aluminum for 17m and then another coil and another part of aluminum for 30m. I would like to know which antenna is it, maybe it is not difficult to know as there has to be not many Warc vertical in the market. I have take the last vertical part of aluminum off, as i donnot expect to use the 30 metres band, and I have taken this off to make the antenna shorter. (I guess it will not modify it's caracteristics onthe 17 and 12 metres band). I took this last part off also because I had to repair the first coil (the one for 18 metres) because it was broken. I glued the plastic part with epoxy glue and I soldered the coil to the aluminum part, anyway I thought it has been not a good solution as I found that the aluminum did not soldered very good. Maybe there is another good solution to repair it in good conditions. Due to this repair I took the last part of aluminum off to make it shorter and maybe more resistent to wind effect. I have also put nylon cord to the antenna.
I have put the antenna just at 1.5 metres over the roof with two radials, one for 12 & one for 17metres band (1/4 wavelenght ground radials made of copper wire). They are parallel to the ground, I mean they are 90° to the vertical element. I do not know if I will notice much improvement if I put the antenna to 3 metres over the ground and if I put two or three radials for each band, also do not know the angle between the vertical radiator and the radials. One problem that I have is that I cannot put the antenna Ok in resonant for 17 metres. I obtain best SWR at 18.700, and I have SWR 2:1 in 18.140Mhz How can I tune the antenna for good SWR at 18.140??? I have tried to longer the radial with no effect.
By the way I thought that the vertical was going to work better than the windom, but serveral times I hear stations with the dipole that I can not hear with the vertical.
Please tell me also which vertical can you recommend if I live in a place affected with high winds in some months of the year and very close to the sea (I can see the beachside from my bedroom window. How

about the magnetic antennas, which first of all seem very expensive?

Fellow Hams!
A small quantity (9 pc.) of a extremely accurate OCXO:s at 5 MHz, ideal as a timebase for a frequency counter or similar project where you want to be exact in time or frequency. These SC-cut owen controlled crystal oscillators have the following characteristics:

Stability (delta f/f): <= 5 x 10E-11 (per day)
<= 1 x 10E-9 (per month)
<= 1 x 10E-8 (per year)
Allan variance: 2 x 10E-12 (1 sec) typical
Frequency adjust range: >= 2 x 10E-7 (total)
Harmonic attenuation: 40 dBc
Output: min 200 mV into 50 ohms (sinewave)
Supply voltage: 12 volts
Supply current: 130 mA (25 degress C) 700 mA (warmup)
Temperature range: -40 - +50 degrees Celsius

They come new in the box with datasheet at $290 excluding freight and handling:

If anyone is interested, please send email for futher details to: joakim@seaview.se

73 de SM0OET
Joakim.

Hi Bill OM,

I have built superhet receivers here. Recently I built an 'R2' direct conversion phasing receiver, as described by Campbell in Jan 93 QST. This is an excellent receiver. (sideband suppression over 50 dB, great dynamic range, and easy to build since it is 90% audio circuitry), and with the right VFO, can cover any band you want. The bare PC board is available from Kanga U.S., and parts are readily available from mail order sources sich as Digi-Key.

GL and 73,
Don, W6JL

Nope Charlie,

Controlled carrier, in the case of the DX60, was added to reduce power
during non-modulation periods.

The DX60 is screen modulated, and screen modulation reduces the
maximum efficiency available at the PA's anode. I believe the
theoretical maximum carrier efficiency is about 30% or so with screen
modulation, rising to full efficiency values only on modulation peaks.

That means the 6146 in the DX60 couldn't run much power on AM with
screen modulation. The cure was to reduce the carrier under
no-modulation conditions.

Controlled carrier modulation is the source of many design problems,
and it certainly does NOT prevent overmodulation.

I remember reading about a 20m VXO CW rig being described as the IARU transmitter. If my memory serves me correctly, the IARU or ARRL had it on show at the 1979 Warld Administrative Radio Conference in Geneva (WARC 1979) to demonstrate to third world governments that amateur radio is not just a rich man's hobby, and that simple and cheap equipment can provide communication.

I'd be inclined to have a look through QST around the late 1970s for info - sorry I can't be more specific.

There is a better one if you can get it;

2SK369 at 2 mA and 1 kHz noise voltage 0.8 nV/(rtHz)
Noise figure at 100 ohms and Drain Current=2 mA is about
4 dB typ. at 10 Hz.
gm is above 25 millisiemens at 5 mA (and the high gm is the
secret of the low noise, along with clean processing.)

2SK371, 2SK170 and 2SK 147 are as good, or nearly so.

I'd use something with very low loss RF properties (assuming the
application is RF), like "Q-dope". You can make it yourself by dissolving
some polystyrene (e.g., styrofoam) in acetone. Be careful with the acetone
-- it's very highly flammable.

Yes as a matter of fact. The Jap 2SK369 is as low noise as you get. A pair of them in parallel yields a noise floor less than 0.7 nanovolts rising to only 1.5 nanovolts at 10 Hz.

What input impedance does the source look like? For low impedance drive, (mixer or phase detector) even a 2N4403 looks pretty good, like less than 1 nanovolt at 10 Hz.

Doug is essentially correct. However, the sidebands do not have a distinctive different frequency from the carrier--they are inherently part of the carrier as the amplitude is varied (increased/decreased) to create what we call modulation. The RATE of change in the carrier amplitude (voltage/current) as a function in TIME is the actual audio frequency usually denoted in cycles change (rate) per second (time). It is this Rate of change which must be demodulated (detected) by the receiver for accurate reproduction of sound. And unfortunantely, in the real world, this Rate change is seldom a single frequency and is, therefore, said to be COMPLEX. 73 Bill N4MXF

Hi;
No, control carrier was not designed to prevent over modulation. And, the mental process of thinking that carrier is changing with modulation is also a bit flawed. Control carrier was designed to be used with low level modulation where the RF amplifier must be operated as a linear. In low level modulation, the amplifier efficency with applied carrier is very low~~30-33%. The efficency actually improves with modulation ~~66%@100% mod. Since the efficency of the carrier with NO MODULATION is so poor and relatively painful for tube heat dissipation, a carrier reduction (from the required reference level) was thought to be an effective means for reducing the heat dissipation required by the tubes in the linear amp. Hence, we tend to think of the base carrier level fluctuating with modulation. In reality, a properly adjusted AM phone transmitter must maintain the correct carrier to peak output relationship. The carrier must be kept at about 1/4 th the PEP output of the amp. The problem with control carrier is the proper transmitter adjustment and receiver detection; many receivers of the day could not adequately detect the rapid fluctuations in the carrier. The CONTROL carrier fluctuations must be isolated from the normal carrier fluctuations which must be detected in the receiver to reproduce accurrately the desired audio or intellengence. I hope this helps--it can be confusing. 73 Bill N4MXF
PS: In modern day receivers, and with the advances in high speed electronic circuits, Is it possible that AM Control Carrier Modulation could have an unfounded niche in Ham Radio.???????????

Envelope = time domain (oscilloscope).

Carrier plus sidebands = frequency domain (spectrum analyzer).

The envelope amplitude varies with amplitude modulation.

The carrier is constant in amplitude.

The sidebands vary with modulation.

The "newbies" and "would-be newbies" are NOT "wanting
it all for free" ... many are technical professionals that this
service desparately needs and all they want is the ability
to participate and contribute without having to waste large
amounts of their valuable time on developing "skill" in an
obsolete technique dating to 1847 when they're employed
at the leading edge of technology and want to experiment,
develop, and build systems using new technologies.

Ham radio would be FAR better off for welcoming these people
with open arms than by trying to keep them out with ridiculous
hazing rituals. The main problem is that most of the incumbents
are so technically inferior to the types of folks I'm talking about
that they can't begin to understand the benefits that they could
bring. And lack of understanding breeds fear, resentment, and
discrimination ... ham radio is in it's "dark ages" ... we need
major changes in licensing requirements/structure, technical
regulations, and ATTITUDES to create a rennisance ...

I am currently in the process of constructing a 14V 20A power supply.
Doing this because I had a Signal 56-4 xfmr and some filter caps already
and don't need another 25# shipping charges. Go to a local electronic
surplus
store and obtain this or a similar xfmr. Think it cost about $15. I
am using
two 20,000 uf 30V computer grade caps for filtering, and two stud mount
rectifiers. These should be at least 25A, 50PIV.

For the regulator, I am going to use three LM338 three terminal
regulators, available from DigiKey for about $9 each. The circuit is
shown in the app note LB-51app. Use your search engine and National
semiconductor for it. And of course you need a large heat sink since
the dissipation = (vin-vout) * Iout. This can be around 100w at
15-20A.

More power to you and your rig,
JimBoros

You might want to look at the datasheet for the J310.
It's N-channel JFET with exceptionally low noise and
high transconductance. It's really an RF/VHF transistor,
but I'd imagine it is even quieter down in the audio range.

Try www.motorola.com : they have FAX-on-demand and you
can get device data from them.

> Is it possible that AM Control Carrier Modulation
>could have an unfounded niche in Ham Radio.?

No, primarily because AM has no place in ham radio except for those noxious, toxic few who insist on polluting the bands with it. But it does have a place of enormous significance in the shortwave broadcast arena where the overwhelming majority of receivers have simple detectors. Almost every transmitter manufacturer now offers some form of Controlled Carrier-Level Modulation. During quiet periods or during periods of low modulation, the carrier level is reduced by 6 db. You wouldn't think, given the high average modulation levels possible with modern audio processors, that much power would be saved. But measurements show about a 20% reduction in power consumption. If the broadcaster is programming with mostly voice, the power savings can be much higher. Most of the CCM circuits in use by the worlds major broadcasters pay no attention to positive peak modulation--it can be 200% if it wants to be. But negative modulation is controlled to -95% within the range of half carrier voltage to full carrier voltage.

The British have come up with their own slant on CCM. They set the PEP output and the carrier is reduced (to a maximum of 6 db) to keep the PEP output constant. This is called Amplitude Modulation Companding and saves power at the cost of signal-to-noise ratio during modulation. CCM saves power at the cost of signal-to-noise ratio during periods of no modulation. But CCM also keeps the modulation index high during low modulation periods.

I have a quantity of surplus state of the art oven controlled crystal
references intended for cellular radio base stations. These have voltage
control and divide down to 1,2,4,or 8kHZ to be used as the reference for
a frequency synthesis loop. These PCB mounting OCXOs are stable to
0.1ppm/year and .001ppm day.
These are for sale @ 20% of the list price. Email me for full spec

There are many off air standards the one I use locks to Allious 162kHz
or Droitwich 198kHZ the propogation effects result in a second to second
variation of 0.01ppm though of course the long term stability is good to
.0001ppm.
If you want good second to second stability your loop time constant must
be very long the best off air standards Tracor? have 1 hour time
constant or longer.
With very long time constants your locked oscillator must have good
medium term stability. TCXOs can have different time constants for the
crystal and the compensating network this results in 0.1ppm changes due
to small temperature variation, better to use a good (proportionally
controlled) OCXO

Douglas Dwyer Frequency Precision Ltd. I design/advise on Xtal osc TCXO OCXO

4952. audio isolation question???

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-10 00:00:00 UTC
From: Jack Reece <bigjr@sprynet.com>
Message-ID: <337508E5.7FE0@sprynet.com>
Source record: 94131

I'd appreciate some help in trying to hook up one speaker or headphones to multiple pieces of communications equipment without blowing the audio circuits in each. Can you just put a certain value of resistor in each line? This may be a simple question to a lot of you but I want to make sure before I blow something.
Thanks, Jack WA0VLT

4953. Manual BK Scope

Today, I bought a used oscilloscope at a flea market. It is a BK
Precision Model 1479, 30MHz scope.

I need a manual for this scope. Does anyone have a manual which they
would be willing to copy for me? Of course, I would reimburse expenses.

Thanks for reading this. Drop me a note if you can help.

Never? This is how the caps are made. They are larger because two caps are
inside the can.
Like this (+cap1- -cap2+). You can cobble together such a cap, but I don't
recommend it either.

>UNIX guru to get working.

>Am I asking for too much?

Have you ever played with Unix or Linux ?

I'm rather new to HAM and packet radio and I have just bought my first set.
For 3 years I have run Linux now and it seems to me the ultimate OS for
packet radio (you have to discover this yourself, NO FLAMES).
I think Linux users/developers and radio amateurs both want to have the
POSSIBILITY to control and to know every little detail.

Unfortunaty using Linux is not common practice in packet radio land. Why ?
I don't know, maybee someone else can explain it to me.

But if you don't bother what's going on, run M$ products and call your
reseller if it's not working. However, I don't think you are a real radio
amateur in that case (perhaps my interpretation of radio amateur is wrong :)).

73,

Gerhard.

Is there any place where an individual hobbyist (not associated with any large 3-letter corporations) can rent a fairly modern spectrum analyzer (Tek 492/494 or similar) for a short time (~1-2 wks), at a reasonable cost?

I need to tweak a homebrew hybrid DDS/PLL circuit for noise sideband performance, and would like to be able to see down to about 100 Hz/division or so between 700 MHz and 1.2 GHz, with an amplitude range of at least 90-100 dB. I could always sell my car and buy a 494, but would rather not. :-) I'm in the Austin, TX area, if anyone knows a good rental place that will take Visa/MC.

tnx -- jm

Hi,
When I am my local mcdonalds drive-thru, if I set my car radio
to 92.5
fm I can hear what the employees are saying on the headsets or what the car behind me is ordering. I was wondering if there was some way I could inexpensively get hold of something so that I could chat along with these people. Or, a friend told me that you can make something which blocks out all radio signals and transmits something you say into a microphone on them. This would be good as I could then listen with my radio what people order then inform them not to because it is crap!

Thanks

DC

You need to keep the source to ground resistor/impedence relatively high.
I use a dual gate mosfet with gate 1 as input for buffering the output of a
high speed DAC on a discrete DDS board. I also usually use a dual gate
mosfet for buffering VFO's with very good results. 1k ohm seems to work
well for the source ground resistor.

If you want to drive 50ohms you need a transformer to get there or add a
bipolar stage after the mosfet.

Rob.

>You might want to look at the datasheet for the J310.

Try National Semiconductors 2N4393 also. Not the absolute lowest in noise but cheap and available. input noise is about 2-5 nV/Hz^-0.5

Oops. I'm sure you already know this but, actually you're transmitting
four times the power which is twice the voltage.

It wouldn't take a particularly heavy investment in tin foil to take a
piece with you, try it out, and see what difference it makes. That is the
essence of experimentation and is worth any number of speculations.

Okay, I've never wired your particular kit, but have some ideas for
you to check out, as I've built several MOSFET-based active antennas.

First, tune to a signal you can hear with the whip attached and set as
short as you can make it. Touch the whip and look for a signal
strength increase when you touch the whip from signal pickup from
your hand. You may also hear buzzing on the signal from AC hum pickup
from your hand. Believe it or not, if this happens it is a good sign.

If that's inconclusive try the same on a frequency with no signal
around (4-6 Mhz), and
you probably will hear a lot more buzzing and noise when you touch
the whip than when you don't.

You should hear these changes if the amplifier is amplifying.

If you don't hear much (or any change), chances are the MOSFET
gate(s) were destroyed by static electricity during assembly (or
possibly before you received the kit, though Ten-Tec has a good
reputation, I've heard from hams...)

(Of course, I'm assuming you've
done voltage checks on the gates, source, and drain relative to
ground, and they match Ten-Tec's voltages. If not, you already
have a wiring or component problem.)

Unfortunately, if the gate(s) are fried, there may be no way to tell based on voltage measurements without knowing the characteristic curves and specs. of the particular MOSFET.

One thing you could check is the current consumption of the kit at full gain. If your kit specs. this, it should be fairly close to the spec. If it's much larger than spec., your gate is probably fried and/or biased incorrectly. Hopefully Ten-Tec can tell you how much the kit should draw from the battery at full gain!

Just my $0.02 worth.

Save your money; photoengraving is a lot simpler. You'll go broke stocking all of the bits that one of those CNC engravers uses and the hold-down jigs required for the various panels you'll be doing is gonna run into a lot of money, too.

If you have a PWB layout package that can produce Gerber plots (there are some public-domain or shareware ones out there that'll work) , you can create the panel on your computer and then photoetch the panel yourself (acid or NaOH for aluminum) or have it done at a plating shop. It's possible to use regular CAD software like QuickCAD, AutoCAD or CADKey to do the artwork and have it plotted and shot photographically at a blueprint house if they don't have something like HPGL-to-Gerber converters on hand.

You can also cut a Rubylith photomask if you're really desperate for something to do; that's how they did it in the sliderule days and the front panels on the old Tek 500-series scopes do look pretty good. Any blueprint shop can shoot the ruby onto orthographic line-art film for about $30; then you're in business.

Either way, you wind up with a photomask that's good for a zillion panels if you take care of it when you're using it.

Nearly all of the WWII and later era panels that have sunken/raised lettering were done with a photoetching process. The neat thing about the sunken letters is that you can fill them with paint for a really professional look.

You can buy a can of photoresist spray-on at an electronics supply house (positive or negative working, take your pick). I think that GC Electronics sells it in kit form. Kodak and Shipley (if Shipley's still in business) sell it in larger quantities but it doesn't keep well and the last time I checked; you couldn't buy less than a gallon at a time. It can be exposed under a shortwave UV lamp and I think that Kodak KPR is exposable under sunlight.

Trust me, a can of photoresist weighs a >lot< less than that CNC mill, requires no CAM programming and your artwork is limited only by the capability of your CAD package.

Message-ID: <33759E35.3B64@online.no>
Source record: 94144

Hi
while emitter follower have a voltage gain of 0.9-0.95, I have bad
experience with source followers. JFET's seems to be best of the kind,
the high conductance BF246 (yfs = 20mmho) is far better than any dual
gate mosfets (with G1 and G2 tied together). All measurements I have
done shows a negative gain of '-6dB' or worse.
Any other experience? I have seen applications where somebody thought
that the DG fet source follower was a good choice, but my experience on
that particular circuit always fail.
Any suggestions based practical experience??

Subject: Newsgroups

Hello Jan-Martin

>I am quite unexperienced with this media, so I find it difficult to find
>all the newsgroups interesting for me. Presently I read the newsgroups
>for boatanchors, homebrew, antenna, antique, equipment etc - are there
>any newsgroups for vhf uhf shf activity and experiments?

Yes, there are several, but they are mailing-lists (sometimes called
"reflectors") rather than newsgroups. The only difference is that you
receive the traffic with your personal e-mail.

Each mailing-list has two addresses:
1. The robot which handles messages to join the list, leave it and other
functions. When you contact the robot successfully it will send you a
message explaining how to use the other functions.

To make initial contact with the robot, the message format is usually

Subject line: <nothing>
Message: subscribe <list name> ; nothing more in the message!

2. A different address at the same place where you send the actual
traffic. If you use the Reply function of your mailing software, your
traffic will automatically go to the right place.

The biggest and busiest list is the VHF reflector at Stanford
University. That generates a lot of traffic!
Send message to vhf-request@W6YX.Stanford.EDU
Message: subscribe

A much smaller European list is called vhf-dx-discuss:
Send message to: majordomo@blacksheep.org

Message: subscribe vhf-dx-discuss
(or maybe that should be join vhf-dx-discuss - if you get it wrong, you should receive an error message containing the correct information)

Somewhere there is also a QRP list which might interest you. It carries too much traffic for me to handle! E-mail g3rjv@gqrp.demon.co.uk for details.

There are thousands of other mailing-lists! If you are interested in power amplifiers, big towers, Yaesu equipment or HF contests I can let you have the addresses. Also there is an EME list which I read.

I don't see the microwave lists, but you could e-mail my friend Roger g4pmk@marsport.demon.co.uk for details.

Source record: 94145

I work for Lockheed Martin in Canada...
All the prototype boards we do are by the photo resist method.
We use GC Electronics positive resist boards (pre-sensitized)
And to obtain the patterns...ACAD drawing of the layout sent to
a Hewlett Packard Laser printer on transparencies.
This method is good for boards up to 8" x 10" for us.
The limiting factor here is what we can fit into the EPROM
eraser (UV light source).
The options are - flourescent light for 20 mins or more..
or sunlight for 1/2 hour or more.
The smallest trace I have ever done is .03", although when I looked
at the final product, I could have gone smaller.
After the board is etched, we always flow the traces with solder.
This strengthens the traces and gives better performance.
Hope this helps.
Bob

I can second this motion. I've been using a medium-sized deep-cycle marine battery and a 3-Amp charger (ordinary linear power supply) for years now. It's a cheap way to go, and you'll never get better quality DC. My experience is that batteries used in this kind of float-charge service last far longer than they are rated for in automotive service.

>alt email 100126.1373@compuserve.com

If you can find a person who has kitbuilding experience willing to
donate an hour or so of time to your efforts, consider the following:

(1) Stereo FM transmitter kit (88-108 Mhz range) RK-FM10 US $34.95,

case & antenna set is an additional $14.95. Takes
line-level input from any stereo component. Requires a
3-12 Volt supply.

Transmitted sound quality is excellent, due to its using
a stereo IC used commercially for feeding CD sound
to an FM stereo radio without CD capabilities in
automotive applications.

If you choose
this option and have a monophonic source, of course you'll
have to use a "Y" cable to feed the left and right inputs so
that listeners with portable "Walkman" radios don't hear all
the sound coming out of one headphone.

(2) Mono FM transmitter kit (up to 1 mile) (80-110 Mhz) RK-FM4 US

$15.95.
Looks like it can accept a microphone (costs extra) or a
line-level input. Consult the manufacturer for details -- I'm

not as confident of the quality of this kit than #1, but the
catalog claims this kit is "great for beginners" [beginning
kit-builders.] No case option is listed.

For the sound source, look at the solid-state "memo recorders"
for sale. Hopefully there is some model with repeating playback

capability. Otherwise, you're stuck with cassette tape loops and tailoring your program to fit one of the available lengths. :(

A third option, if funds are available, is to record a CD with the program as a single track. Most CD players can be set to replay one track over and over. I think this option will cost the equivalent of a few hundred dollars US. Advantage is that sound quality will not degrade over time, and the message can be of any length from seconds to 75 minutes long. Of course, with either tape or CD option, equipment wear-out will eventually occur.

Source for kits:

JDR Microdevices
1850 South 10th Street
San Jose, California 95122-4108
1-(408) 494-1400. US&Canada 1-800-538-5000
International orders are no problem. Questions:
intl@jdr.com

Web page: http://www.jdr.com/

I am not affiliated in any way with JDR, just an intensely satisfied customer. (Why else would I bother to look all the above information up? ;) They are one of the best retailers of kits and "nifty" chips I have been able to locate, and their catalog is a lot of fun to browse through.

Hope these ideas help.

Hi folks,

I'm sorry if this isn't an amateur radio question BUT it is a question about radio reception and you guys are good at pretty much anything that has to do with radio so here goes:

I work in a large room that is full of computer terminals and florescent lights. Needless to say, the reception on both AM and FM is not very good. But, they do allow us to take our Walkman's to work and most of us can get 3 or 4 stations... all FM.

However, I will soon be located close to a window and know that I will be able to get 2-3 AM stations over there by placing my Walkman on the sill. I've noticed that reception improves even further if I pass my hand over the radio cutting off the florescent light interference. My queston is: Is there anything I can take to work with me and place over the Walkman that will cut the lighting interference? Would tin foil or heavy cardboard do any good?

Thank you very much,

Bill

Source record: 94151
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.equipment

I would like to connect my computer to my IC-706 transceiver, but I need the cable to connect the computer to the radio. MFJ sells the MFJ-5383i cable for $49.95, but I'd rather build my own cable.

(1) Can anyone direct me toward a schematic/wiring diagram for doing so? and (2) I prefer to connect the cable to my serial port; does the MFJ cable connect to the serial port or the parallel port? If I must use the parallel port, I will.

Many thanks,
Rich, KB2ZMF

Check out the new website on the net! N9SBV's Ham Radio Connection at Http://members.tripod.com/~n9sbv/Status.htm

This new system is oriented toward helping the new ham radio operator with resources he or she may need to get the most out of their hobby.

Lots of shareware available for download from the FTP Site. With 2 of the NEC 7 disk Changers online for starters, there is over 15 Gig online of all types of shareware software.

The WebServer is focused on Amateur Radio Related Areas. Homebrewing, Weather, RACES, FCC Rules and Regs, general Ham Radio Aids, and the like. And if you would like to put up a home page at the site....well I may even be able to accomadate a few users for that purpose. The site will be maintaining a Ham Radio focus however.

This site is located in South Bend, Indiana. It's my hope that it will become a major link for Operators in the Michiana Area to keep in touch locally and worldwide.

See you on the site!

I got this from OCF on line. Please forward, Thanks, Anne

I checked the phone number, it is definitely Chrysler, but they are only open business hours.

Please pass on--Many friends were left off because each of you could pass on to more mutual friends than I could.

In a message dated 97-04-25 12:16:47 EDT, you write:
<<
Chrysler had pulled their ad from the TV series "Ellen" that's got a
woman who's coming out as a lesbian. They are trying to see if
there's much support for doing so. I would encourage you to call
their number--1-800-992-1997. You have to wait about 90 seconds to
get to a real person and then you can tell them something like,
"Thanks for having the moral character as a corporation to withdraw
your support for the Ellen show." They will ask for your name.

You also might want to pass this on to other friends and email lists
and encourage them to do the same thing. We need to flood their phone
system.

Gary,

Thanks for the reply, but I'm still unable to find any useful info.
I've downloaded John Hansen's (WA0PTV) radio control program, but
there are no plans to build the cable...he only recommends purchasing
the MFJ cable. Subsequently, I found a small circuit which converts
the RS-232 voltages to TTL levels and back; however, the circuit is
somewhat illegible and the broader context for its use is not
described (i.e. how does it get inserted in the cable between the comm
port and the XCVR port?) BTW, I found this at
http://www.synapse.net/~kentrol/ under the "PC Interfaces" menu,
"Level Translators" paragraph, "schematics" hypertext keyword in
paragraph.

I also noticed that the program I have will not work with Win 3.11,
which is what I have loaded on my notebook computer.

So at this point, I still need a circuit schematic, wiring diagram,
and additionally, the names/sources of some additional
shareware/freeware control programs (for both Win 3.1 and Win 95).
Sorry to pester...but please help...

Many thanks...

Best Wishes,
Rich

The radio uses Icom's CI-V buss architecture. This is a party line buss
driven by OC drivers at TTL levels, IE it's sort of like ethernet. Icom sells
an interface which can break that out to RS232 serial, but it isn't cheap.
For controlling a single radio (the buss can control several, all daisy chained),
you can build a circuit to convert to RS232 levels and split Txd and Rxd for the
serial link. This circuit is a couple of transistors and a diode. MFJ builds this
into the cable. You can wire it up on a piece of perf board tucked inside the
DB connector of a homemade cable.

The circuit is included in the documentation for several of the shareware and
freeware programs you can use to control the radio.

I just got a GENERAL RADIO 20,40,80 meter Tube type X-mitter with plug in coils at our local ham-fest. I am very intersted in building a Tube type receiver. If anyone has plans for receivers, and access to a photo copier... I would be glad to send postage, etc..

Plans have to be super simple.... I am just now learning about transitors tank circuits.... and when I saw this beautiful lil' glow in the dark x-mitter.... I knew I had to change my course of study! :)

Thanks in advance for any assistance you may lend,
Marty KF4HTL ngcbwo@infoave.com

Hi, we'll get right to the point. We operate one of the finest quality custom color labs in the USA. To introduce you to our service we're offering the following Internet enlargement special:

Your color negatives hand printed on Kodak Supra Professional 16x20 inch paper. All negatives printed full frame. Exhibition quality and color corrected---send us any size color negative (35mm up to 4x5 inches).

* * * * * * * * * *

16 x 20 inch color enlargement special
5 identical prints from same negative-------$79
10 identical prints from same negative------$129

* * * * * * * * * *

Most orders 1 to 2 days in the lab. Add $6 priority mail shipping; international add $10. We accept Visa and Mastercharge.

Mail your negative(s) and payment to:

TSP CUSTOM LAB

>Any suggestions based practical experience??

To a first approximation, the output impedance of a source follower is 1/gm. So your BF246 will have an output impedance of about 50 ohms. Bipolar transistors have a very high gm, and correspondingly low output impedance. The low gain is probably due to the combination of output and load impedances (the latter including the source pulldown resistor) forming a simple voltage divider. You can take eliminate the loading of the source pulldown resistor by substituting for it a matched FET with gate connected to drain. (That is, the new FET is matched with the source-follower FET, for IDSS.) This "totem pole" circuit has the advantage of near-zero offset voltage from input to output. (You'll find this at the vertical input of many Tek 'scopes.)

You've apparently already discovered that higher-gm FET's do best. There are FET-bipolar combination circuits which can give the best of both worlds, with an FET at the input and transistor at the output. One of the most common, however, tends toward instability. The FET drain is connected to the base of a PNP bipolar transistor and a resistor to V+. The PNP emitter goes to V+. The PNP collector is connected to the FET source and a resistor to V-. This is also the output terminal. Input is the FET gate. Various methods can be used to stabilize it depending on the characteristics of the transistors and the frequency of operation.

Simple way to keep things very cheap and reasonable quality: Buy an old
450MHz-band pager receiver...expect to pay about $10, maybe less. Get
one that uses one of the common FM IF/detector ICs that you can get data
for. Recrystal it and hack the detector output to an audio amp. Ones
I've gotten I can easily add squelch to, and something like an LM380 or
LM386 takes care of the audio amp. Sometimes you can find batches
of pager receivers all the same, if you are looking to make a bunch of
these. That would have the advantage of letting you replicate the same
hacks after you figured out the mechanical and electrical stuff for one
of them.

: 4 dB typ. at 10 Hz.
: gm is above 25 millisiemens at 5 mA (and the high gm is the
: secret of the low noise, along with clean processing.)

: 2SK371, 2SK170 and 2SK 147 are as good, or nearly so.

Thanks to Bob for these recommendations...but I suspect Anders should
have mentioned that the signal source is a capacitor microphone, and
at low frequency, the noise current will also be a consideration.
Are these parts good for low noise current as well? At 10Hz, the
source impedance Anders is dealing with may well be around 10^9
ohms. (Obviously this precludes using a bipolar as others
suggested.)

5000. IC Announcement

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-12 00:00:00 UTC
From: Todd Peterson <elab@netins.net>
Message-ID: <33777294.197C@netins.net>
Source record: 94079

Integrated Circuit Announcement

We are pleased to announce the addition
of two unique new IC's to our product lineup:

EDE700: Serial to LCD Interface IC - provides a
serial link(2400/9600 Baud) to most any LCD display.
Offers standard horizontal shifting & new vertical
scrolling, as well as custom character generation.
Data can also be read back from the display serially
for use in limited-memory systems. $15.00 Qty. 1

EDE1400 Serial to Parallel Printer IC - allows serial
data (2400 Baud) to be printed on a standard parallel
(Centronics) dot matrix or thermal printer. Great for
any application requiring hard-copy of data without
PC intervention. $13.90 Qty.1

Both of these 18-pin IC's are great for microcontrollers,
BASIC Stamp(tm) users, or OEM designs & come complete with
a printed datasheet fully explaining their operation & use.
For further information & PDF datasheets, see our web site:
http://www.netins.net/showcase/elab
Look in the 'Integrated Circuits' section.

Date: 1997-05-12 00:00:00 UTC
From: toms@inconnect.inconnect.com
Message-ID: <5l5p2s$s7m$1@news.inconnect.com>
Source record: 94080

Has anyone built the level converter in the station accessories section of the 1996 Handbook? This is the one that has the TTL/RS232 interface for all major radios. I remember seeing something posted somewhere about some rework required to get it to work with ICOM radios. Also, it is my understanding that the buffers are not required. Thge actual ICOM product only has the MA232 chip. (Actually, I have several versions of this chip some which do not require the discrete capacitors).

Any insight would be helpful.

Hi Jim,
Just let me know when you can hear europe on 160m and I'll call you from
the mobile and you can hear my amp!
I recently imported an SGC cube which seems to run just fine so if this
is in the budget give them a call, alternatively you'll find both Henry
and KLM supply HF all band mobile heaters that'll give you nearer a KW,
it's just that they don't advertise these much, I wonder why!
Also just completed my first RF Electronics 1.8-30Mhz home brew kw (only
allowed 400w sic) home brew, and you'll find him in Myrtle Beach, SC
plus QST.

For driving a low impedance load, the best approach that I've
found to date is to use what is know as a bootstrapped source follower.
Here, a PNP bipolar is added to the circuit. The drain is connected to
the supply by a resistor, possibly with a choke in series. The base of
the PNP device is connected to the drain, and the emitter to supply with
an appropriate biasing resistor, as well as AC bypassed to the supply.
The PNP collector is connected to the FET source. If the drain to supply
impedance is sufficiently high, this has the effect of multiplying the
gm of the FET by the hfe of the PNP bipolar.

For a thorough treatment of this circuit, see:

5014. Etching Panels

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-13 00:00:00 UTC
From: "Barry L. Ornitz" <ornitz@tricon.net>
Message-ID: <01bc5f53$eaf54c80$LocalHost@ornitz>
Source record: 93958

Geoffrey Schecht <geoffs@onr.com> replied to an original post by Bob Duckworth, WB4MNF, about panel engraving:

> Save your money; photoengraving is a lot simpler. You'll go broke
> stocking all of the bits that one of those CNC engravers uses and the
> hold-down jigs required for the various panels you'll be doing is
> gonna run into a lot of money, too.

He then wrote some useful, but very outdated, information about photoengraving and photoresists.

Most "photoengraving" of electronic panels today is really a photo-anodizing process. Either the colored anodizing on an aluminum panel is dissolved away, or in high-production runs is applied to a blank panel. The deep engraving of the past has almost disappeared in today's modern world.

The idea of using a CAD program to generate an original panel layout is certainly a good one. A Gerber file is rarely necessary as today's inkjet and laser printers usually have quite adequate resolution for most panels. Negatives can be shot directly from your original on paper, and you can often print directly on transparencies.

Using printed-circuit photoresists is possible IF you know what you are doing. Not all photoresists are capable of withstanding both acid and caustic baths. The modern dry-film photoresists typically develop in mild caustic and dissolve in strong caustic baths.

KPR (originally Kodak photoresist) has not been made by Kodak for years. I believe they may have sold the rights to Shipley. It seems to keep extremely well as I have three bottles of the concentrate from back in the days when Eastman Chemical was part of Kodak. KPR can achieve really fine details but I STRONGLY suggest the amateur stay away from it. The material is extremely toxic and it contains known carcinogens both in the resist itself and in the developer (mainly monochlorobenzene). Unless you have the proper safety equipment including respiratory protection - stay away from it.

If you have access to a laminator, the dry-film resist is easy to work with. The developer is safe and relatively mild. I suspect some of the "iron-on" resists for home use would work well too. I have used the dry-film resist and mild hydrochloric acid to etch lettering into a brass plate successfully. I used an acetate transparency in a laser printer to expose the dry-film photoresist. You often need to play with the font styles and sizes as the etching can undercut the resist.

Remember when etching metal to not use the same etchant as you do for copper circuit boards. Also remember that acid etching releases extremely flammable hydrogen gas. Strong caustic etching of aluminum is possible but you have to have a resist that can handle the caustic. Agitation of the bath during etching is important.

>
>73, Bill W7TI

If you tune in to the carrier frequency with a sufficiently narrow filter,
you will hear a continuous carrier. In fact if you had a variable bandwidth
filter, and perfectly accurate measuring equipment, you could observe the
carrier variations drop off and tend towards
a constant carrier, but never precisely constant, as the filter bandwidth
tends to zero. Of course if you had a zero bandwidth filter, the time
delay through the filter would be infinity. Therefore, in a finite universe
(timewise), you can never observe a truly constant carrier.
Is it the carrier itself that remains constant? If you have a varying
carrier going through a very narrow filter, it is known that the response
of a filter to an excitation of higher bandwidth than the filter causes
it to "ring" at the centre frequency. So, you could say that there is
no constant carrier- it is the filter that is ringing to fill in
the modulation. Whether you model this mathematically as a set of
line sidebands being selected by a filter, or a varying carrier causing
a filter to ring, amounts to the same thing in the end.
It is perhaps a bit like the dilemma of describing a photon as either
a particle or a wave. It has elements of both- depending on which way
you look at it.

To Barry's good words of wisdom, I'll add some of my practical experience in the area...

Back when I was a graduate student, as a sideline I made front panels for a smallish high-quality consumer stereo manufacturer. The panels were (are) black anodized aluminum, the lettering showing as aluminum color. The font used was a fine serif font, and the manufacturer wanted to maintain detail int he serifs. The process I used I spent quite a bit of time on, to get it repeatable in my kitchen. Over about four years, I probably made close to 10000 panels...keeps one off the streets in the evenings.

My process was to coat the anodized panel with photoresist. I used Shipley AZ111 (later AZ111S). It comes as a lacquer. It develops in nominally 0.3 molar hydroxide. Since it's very hard to coat sharp edges well enough to keep them from etching, I did the development AND etching using a single application of a "puddle" of developer/etchant on the areas where lettering was to appear. Control of the photoresist application, drying, exposure, developer concentration and temperature, and develop/etch timing resulted in high yield...I really hated reworking panels, because it meant re-sanding and re-anodizing them. Note that there was no agitation involved, and no strong caustic etching. 0.3 molar is strong enough to dissolve the anodization layer. A finishing touch was mild scrubbing with a fine-bristle brush before the photoresist was removed. (Brighter lettering resulted from using a little Comet or similar cleanser with the brush...but wasn't normally

worth the effort.) It was very important in this process to properly dry the photoresist after it was applied to the panel. Baking (at about 150F) for half an hour was necessary, not optional. A day of curing after baking helped considerably, but the process could be "rushed" without the curing if other steps were controlled very carefully. I did some experimenting with post-development baking of the photoresist at higher temperatures, and found that indeed, as Shipley's ap notes said, the resist became much more chemically inert...the highest temperature baking results, as Shipley says, in a coating which is very difficult to remove. (A very long soak in MEK, as I recall, softens it a little.)

A couple words about the aluminum: When I was getting started, I visited the local anodizing shop, Anadite, who over the years did very good work for me. I asked about alloys that would give me a good deep black, and they recommended 2024-T3. So, I ordered 2024-T3 for the panels. Indeed, it gave very consistent deep black from Anadite, and I discovered along the way that the anodize layer on that alloy for "normal" processing is about 1/3 as thick as for other more common alloys. That bit of good luck saved me a lot of time: when I processed other alloys, I found they took about three times as long to etch, and for best results required baking the photoresist after development so it would hold up for long enough. Also, the 2024 alloy resulted in finer detail in the lettering. But when I moved and didn't have an Anadite division close at hand, I found that 2024 was exceptionally hard for most shops to anodize without doing nasty things to it: ending up with pits in the surface or streaks in the finish or other problems. Ended up actually shipping the panels to Anadite!

For those that like to experiment: I found that Ferric Chloride, as you'd use to etch a circuit board, etches anodized aluminum pretty quickly. However, it doesn't leave the exposed aluminum surface bright. Also, ferric chloride will etch many stainless steel alloys.

My experience with the Shipley AZ111 lifetime is similar to Barry's with KPR, I guess...I'm using the last of a quart I bought in about 1981, and it still works OK. Was stored dark and cool most of the time.

But the filter is simply a way to observe the system...the behavior of
the system is independent of the filter used to observe it. The math
says the carrier remains constant amplitude, and you can make
measurements that match the math within the accuracy of your system and
your measuring tools...you can also use a filter with only zeros to
observe the system, without ringing, and see only the carrier, assuming
you have put zeros exactly on the sideband frequencies. You don't have
to measure a practical system very long to exceed the dynamic range of
any realizable instrument. (I regularly make such measurements, and
when I need to, do it to in excess of 140dB dynamic range. I can also
implement an amplitude modulated signal and spectral analysis tools
entirely within a DSP or other processor and get much greater dynamic
range.)

This subject has always been a "gripe" with me. For years I have
heard lecturers and hams talking about a "modulated" carrier. When
in fact, the carrier is not modulated at all. The carrier remains at
a constant amplitude, regardless of if you talk or if you don't.

The mistake people fall into is that they speak of the
"AM Envelope" as if it was a picture of a varying carrier. The
"AM Envelope" is a COMPLEX signal, containing more than one frequency,
therefore you cant make any comments about single frequencys in
that envelope.

The equation for an AM transmission of carrier frequency (wf) with
modulation frequency (wm) is :

AM(t) = sin(wf)t + 1/2cos(wf - wm)t - 1/2cos(wf +wm)t

This equation shows that the carrier does not change at all,
but the sidebands of the carrier do. However, depending on our
definition of "modulation" we may say that the carrier is modulated
with our audio tones, etc.

However, my point is that if anyone simply points to a
"AM Envelope" stating that here is a picture of a carrier changing
with the modulating frequency, they are wrong.

Hope this sheds some light on the subject.

Regards,
Luke

Hey Gange,
I need some information. I have a Rockford Fosgate of a friends that is a Punch 45 HD Mosfet. Someone has let the speaker wires touch and burnt some transistors up I think.

The transistors are the BUZ R238. Any help is much appreciated. Thanks,
Matt, AE4JM

I hear you :) I have some books that have some tube receivers, ranging
from simple AM to Ham Band Regen's. If you give me your address, I'll send
a photocopy. Or, one of the books is only a $19 dollar book that I got ad
the local Media Play. It's Called "Radio Receiver Projects You can Build".
ISBN 0-8306-4190-4. It's by Homer L. Davidson. I recommend just buying
that book. Has 33 projects in all, MANY of which use tubes.

Seeing all the paranoid ads about software piracy is strange. If you deal
with Motorola Semiconductor uP applications, they give software away for
free and hardware on the cheap. Funny how different divisions can be so
diametrically opposeed.

You CAN run it off a 9V (look at the picture)

> 10k ohm resistor
> xtal (by the way, where can I get a 40 meter crystal?)

You can get 40 Meter Xtals from Norcal
(http://www.fix.net/~jparker/norcal.html)

> 365 pF variable capacitor
> loops (needs explaining)

If you read the text, the loops are explained. It has a table with the
number of turns to use and it says to wind them on a film can (or other
1.25" form). It says use 20-22 AWG enamled wire. You can pick up a nice
assortment of enamel wire from radio shack for $3.99

> antenna, grounded
> ?????? (unknown, two parallel lines, looks similar to capacitor, labeled
"0.05")

Yes, that's a capacitor. It's a slight variation on the standard symbol.

please refer to as "Y"
> ground
> NPN transistor
> ?????? (unknown, rectangle w/ "s"s in it, labeled "27") <---please refer
to as "X"

It's a resistor with a value of 27 Ohms. Again, a variation on the
standard sybol.

5027. 5/8 up and 5/8 down antenna ??

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-13 00:00:00 UTC
From: Kip Martin <sl0ym@cc.usu.edu>
Message-ID: <3379446E.1547@cc.usu.edu>
Source record: 93971

Hello all,

I was wondering if a home made diepole of 5/8 length could be built and
matched with a matching network ?
I want to hang a diepole with the 5/8 elements instead of the 1/4.
Theoreticaly, I have heard the 5/8 in a diepole has more gain than a
ground plane configuration. So does this imply a 5/8 up and down
diepole may out perform the maico ?

>Thanks,
>brianb@hughes.net

If your HT has a BNC connector on it you can get a 1m length of
coax with BNC connectors on the ends and a BNC tee.

make a loop of the coax and put it in the ends of the tee.
when you are ready to use it, you will just plug the side of the tee
into the HT.

BUT FIRST, clean an inch of the shield off the top of the loop,
which is the middle of the one-meter length of coax.

open one end of the coax and cut the center conductor and patch
the shield to the center pin of the BNC connector.

Badly said, I know, but it will make a useable DF antenna. Only takes
a fews mins, too.

It can be improved quite a bit, and that not hard, but this will get
you a start.

Go to used book stores and look for old ARRL handbooks.
Many antenas are there.

Go to the public library and look for old radio magazine articles.
there are a great number.

If your library doesn't have the stuff, they can get it on loan.
Ask them.

Good luck.

From: KA8YKK <KA8YKK@concentric.net>
Message-ID: <3378D2AA.71F6@concentric.net>
Source record: 93974

Please forward to all amateur radio operators

I am circulating this petition across the state of Michigan. Anyone wishing to join in on this petition can change it from the state of michigan and change it to their own state. You can also down load it off my web page http://www.concentric.net/~ka8ykk

Amateur Radio Operators
>From the State of Michigan
We the Amateur Radio operators from the State of Michigan do hereby agree to continue to abide by all the rules of Amateur Radio. We pledge to improve the amateur radio bands, and teach new hams joining the hobby the correct operating procedures which should be followed on the amateur bands. By doing this, we are petitioning the American Radio Relay League in our fight to help clean up the language on the Amateur bands, and are looking for civility/politeness in conversations. By showing our support in this petition, we are hoping that the American Radio Relay League can help us fight the language that we are hearing on these bands.

We are asking the American Radio Relay League to help in this clean up by: Hosting several national forums on this problem, and how it can be addressed, We are looking for a promise from the ARRL to report on how enforcement is currently done. We are also looking for a promise from the ARRL to create a sort of self enforcement mechanism, and possibly create a large fine mechanism that will generate enough money to help correct this problem. We realize there is such a thing as freedom of speech but, there are also the words such as civility, and politeness.

I Deborah K. Kirkbride KA8YKK am asking all amateurs in the State of Michigan to please sign this petition, and send it to me at the following address: 1315 Center Avenue, Apartment #1 Bay City, MI 48708. I will in turn when enough signatures are gathered be sending all petitions received to the ARRL.
Please make copies of this petition and pass it along to other clubs, and Amateurs in you area. Please help me in this fight to get the Amateur Bands back on the right track and keep them there.

73 deb ka8ykk

And you are dogmatic and didn't pay much attention to the
table of trig identities.

(1 + sin(wm)) * sin(wf) is equivalent to your expression.
(envelope) (carrier)

You can factor it to emphasize the spectrum or emphasize the
carrier and envelope, but they are the SAME equation.

The times I've rented test equipment, the minimum rental time was one month and the cost per month was just about 10% of the new price of the instrument. If this is "reasonable", you probably have several rental company choices. If not, I don't know of a rental place for you -- perhaps some other folks do.

I'd be surprised if you'd find anything as old as a 492 or 494 at a rental company.

I don't know which edition of the handbook you are reading, but
I worked on the chapter on modulation used in the 1995-1997 books
along with Dave Newkirk. This question prompted more discussion
than anything else in the chapter. I don't think there is any
really good way to explain this intuitively. You can, of course,
define everthing rigorously in mathematics and prove it. But as
Dave N. used to say "equations don't teach". So you may find
what we wrote to be unsatisfactory as well. However it was not
for lack of awareness. If anyone feels they have a really good
explanation, submit it to the ARRL and maybe it will be in the
next handbook!

I wouldn't pass up scouring the local public libraries. A lot of
times, an old copy of the AARL Handbook is all they have,
since funds are so limited these days... :(

I assume your ham friend is aware of the lethal nature of
the voltages involved in tube circuits, the need for bleeder
resistors, proper isolation from ground, etc. etc. When I was
experimenting with tube circuits in high school, aware of the
dangers, I got a nasty 360 volt shock despite the fact that I
was standing on a wooden stepladder and one hand was
in my pockets. How? The insulation on my multimeter had
been burnt accidentally with a soldering iron (unbeknownst
to me), and I must have touched the weak spot in the insulation
at the same time I was measuring plate voltage on the final.

For my $0.02, i'd encourage him to play with FETs (VMOS power
and small signal or MOSFETs) instead. Similar operation,
but battery powered and portable and not likely to blow him up.
For that matter, aside from multi-hundred watt RF, tubes are
virtually never as good as solid state. A 6L6 isn't going to
produce enough power to bother with tubes anyhow!

Ross

Body handling: HTML body converted to readable text

http://www.hamradio-online.com - the all volunteer, online ham radio magazine is now read in 65 countries. Some of the feature stories we have now include:

Ham Files Suit Claiming He "Owns" An Amateur Radio Frequency
In an ongoing dispute in Southern California (USA), Ron Ames has filed a lawsuit against the Keller Peak Repeater Association (KPRA) claiming ownership of a sanctioned and coordinated repeater frequency.

13cm PSK transceiver for 1.2Mbit/s packet radio
Here, Matjaz Vidmar details his design of a 1.2 million bits per second digital radio for Amateur use.

Simulated Satellite Projects Using High Altitude Balloons
Operated by NASA in conjunction with AMSAT and local amateur radio groups, this project simulates many of the practices and remote observing challenges inherent in working with real satellites, and offers a unique hands-on experience for students in K-12 earth science, physical science, physics, electronics or aerospace classes.

Equipment Options for Medium and High-Speed Packet Radio
Here is an excellent summary of the hardware options available for constructing medium- to high-speed packet radio links (9600 bps to 56 kbps and beyond).

Ham Radio Operators: Communications of Last Resort
The Grand Forks North Dakota Herald reports on amateur radio in the flood stricken Red River Valley.

Discussion on Sunspots and Earth Climate
The sun-climate connection is something that's been talked about many times. It's like everybody knows there has to be some connection but no one can prove a good case. This time the evidence seems pretty compelling and we have a better handle on Earth's climate past.

And many more articles this month too!

Plus the best propagation resources you'll find on the Net; equipment specifications; product directory and other sites lists; disaster situation updates and so much more.

This is a free web site, run by volunteers. No ads. Since October 1995. There is a reason this is the world's leading amateur radio web site. Stop on by and enjoy!

5039. 28MHz SSB/CW rig

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-13 00:00:00 UTC
From: pavel.reberc@guest.arnes.si
Message-ID: <5l916resc1@kanja.arnes.si>
Source record: 94098

Hello,
I am searching for a modern design radio for 28MHz band
with good receiver performance for use in VHF contest conditions with
a modern transverter for 2m in front of it. I already have built
transverter, but i think it is stupid to buy far-east toy with
flashing front pannel for >2K US$ and terrible receiver performance.
(IP3 / Sensitivity /NF)
I have found some designs for receivers, but i need transmiter too.

Thanks for any info.

5040. Seeking help in identifying specs for vaccuum fluorescent display

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-13 00:00:00 UTC
From: Ron Tsur <ron@lynx.coredump.com>
Message-ID: <3377BA4D.6F0C@lynx.coredump.com>
Source record: 94099

Fellow experimenter,

I recently purchased several vaccuum fluorescent display modules from a
local surplus store. unfortunately, the store could not provide any
data about the display modules (in fact they did not even know what they
were...). I tried to identify the units by scanning through catalogs,
but it was all in vain.

Here is an obseravatory description of the module:

General: 20 character 5x7 matrix
Dimensions: 1.25" x 6.0" x 0.75"
Designation: ISE Electronics Corp. - CU205SCPB, Made in Japan
Connector: 13-pin single-in-line header type

Parts Identified on PCB assembly:
DC-DC converter (using discrete parts)
SED2000 (display driver? - large surface mounted IC)
NEC 80C42G (microcontroller?)
12 MHz crystal
Multiple surface mounted transistor, resistors, caps

I would appreciate any information that would help make good use of
these displays. An interface spec or full data sheet will be excellent.

Thanks,

Ron.

Anyone building NN1G's QRP SSB rig as featured in April QST ?
I ordered the bare board (pretty good quality !!) and am in the
process of populating it for use on 20M.

I've also been thinking about using it with my Ten-Tec transverter
on 6 meters, hopefully in time for the upcoming Es season.

You aren't cutting off the fluorescent light interference, you are
augmenting the antenna.

> My queston is: Is there
> anything I can take to work with me and place over the Walkman that will cut
> the lighting interference? Would tin foil or heavy cardboard do any good?

Try a larger antenna -- there are passive and active ones out there. A
big loop in the window, resonated with an old 365 pF broadcast variable
capacitor. Don't know if you could place your receiver next to it, or
whether you'd have to make a separate coupling loop.

Experiment!

check out

http://www.fix.net/dans.html

he has some trimmers, but nothing in the 1000 pf range. i'd really advise against using a trimmer. if it is a set once and forget situation, used fixed values, with a small (40 of) trimmer. if you are going to be twiddling it a lot, an air variable has much better adjustment.

>(IP3 / Sensitivity /NF)

I do not know which brand you refer to, but if you have a receiver
design that even *remotely* matches the performance of e.g. the TS850,
without needing 1000$+ worth of components, please let me know.

>I have found some designs for receivers, but i need transmiter too.

The transmitter is comparably trivial, use your RX-LO chain, a mixer,
filter and off you go.

The large guys are expensive.

Try to find a local "instrument repair" and calibration house, one that
serves local
companies. They frequently have stuff for sale or rent and you can
sometimes
do quite well. Look in the yellow pages or ask around.

These are good people to get friendly with!

The best thing to do is buy a JBI universal radio interface kit.
The JBI kit is reviewed in Dec 96 issue of 73 magazine. I bought
two just as the author of article did and they work great.
There are 3 articles in QST magazine relating to computer interfaces
all good reading. July 92 "A Low-Cost PC Interface for ICOM Radios"
Feb 93 "Everything You Always Wanted to Know about Hardware for
Computer-Controlling Modern Radios" and Sept 91 "An Inexpensive
Computer/Radio Interface". Hope this helps. 73, George K5GH

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
May 18th, 1997
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >1000 cars!

Buyers admission is $4 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $10.00-each at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Seperate lines will form prior to gate opening
for prepaid and nonprepaid vendors

A discount sellers SEASON PASS is available for
$50 per space if purchased by April 20th.

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 146.52 and W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society

Does anyone know the contact ratings of a Jennings RJ-1A relay at 4MHz? I'm interested in using one to switch mobile loading coil taps on 40/75 meters and need the capability to switch (dry) about 10 amps and have a standoff voltage of around 10 KV. I think the RJ-1A is only good for about 5 KV but don't know for sure.

Thanks,

bart wb6hqk

As a one-time motor/transformer.coil rewinder for pay, let me ask you,
is the original lwire still on the solenoid you are to rewind?

If so, you might be well served to do what we used to if we had not
the original specs: We counted turns. Put it on a spindle with a
counter attached, and start pulling the wire off. Not too fast, since

if the wire is burned or breaks, you don't want the monentum to give
you a false reading.

The wire size and the turns count will give you an exact report.

However, if you take the outer diameter of the solenoid, the O.D. of
the spool, the size of the wire, and the thickness of the insulating
paper (if any), then you can use 8th-grade schol math to see the
number of turns.

That will put you well in the ball park.

Correct Resistance will follow as the day follows the day before.

John:

You may want to try a place I've used called Naptech in CA that's a fair amount cheaper than Tucker or Test Equity. They've rented older equipment to me on a monthly basis. I think it was 10% of their current sale price per month. They take MC, I not sure how they handle security deposits, I've always had enough available credit on my card to cover it.

I checked their current catalog and they list TEK analyzers back to and including the 491, 492, 495, 496. You mentioned the 492, I checked their last catalog and the purchase price is 6,900.00 so it won't be real cheap to rent. They also stock a bunch of the HP and some Avcom analyzers that are cheaper.

The stuff I've gotten from them has been clean, calibrated, and with all probes and manuals.

Their number is 800-336-7723 and I think they have a website now but I would just call.

good luck,

John Emerick

I have just aquired 2 Vector-2XG Digital Compass Units which are brand new and still in the box. Originally I was going to uses these in robotics, but have recently obtain a GPS unit to use instead.

As they are brand new, in the box, never used I am asking $80.00 for each one. Original cost was $99.00 in quantity.

These units are the top of the line model with full gimbal mounts which will compensate up to 15 degrees of til in either X or Y.

Marty - you may not even need to do that - receiver designs and articles are available on SM0VPO's Homebrew Home Page. There's several simple receivers - valve and transistor. A link to SM0VPO's page is provided on the Australian QRP Home Page. You can reach that by going to my home page (see URL below) and selecting QRP.

Gentlemen,
I have a question for anyone that may have experienced "crackling" noise on their VHF repeater when the wind is blowing. Here is the scenario. We were donated a spot on a wooden utily pole which sticks out of the ground (the earth here is rock with a couple inches of soil over it) about 85 ft. There are 4x4 wooden cross arm systems at a couple places on the pole. At each cross arm there are 2) 4x4's bolted through the pole
with u-clamps at the ends. This is where the 2" pipes are clamped to the 4x4's for the antenna mounting. All 4 UHF machines work well. No noise. The VHF one does not. If the wind blows, the noise gets so strong it kicks incoming signals right out of the repeater. We have checked all antenna and feedline connections. They are good. What we did find was that if we wiggle or touch (with metal object) any (!!!ANY!!!) metal parts on the 4x4 support angle irons, 6 ga lightning ground wire which runs from the antenna mounts to central pole wire and down, pipes, anything metal at all, the noise is horrendous. What we suspect is that due to lack of RF ground, there is a pretty decent RF voltage/current, whatever, flowing or present on all the metal parts up there. If every piece of metal was bonded together and we nail copper flashing to the pole to connect RF grounds to, would this get rid of the dreaded "cracklies"?? How can we get a decent RF ground for VHF in the earth on top of this mountain? Any ideas would be more than greatly appreciated. Thanks for your help.

George

> on 6 meters, hopefully in time for the upcoming Es season.
>
> Hugh VA3TO

Just finished it from the complete kit. Working great today (the receiver does a really great job). Had a brief problem with the transmitter lineup but traced the problem to the "test" pin header, where the right pin hole (as viewed from front of the board) apparently was not plated completely through between the top and bottom traces, leading to lack of audio drive to the first mixer. Make sure you have that pin soldered to both top and bottom traces!!

Do you know if there is a QRP newsgroup or how to contact other SSB QRPers for scheds, etc ?

On Tue, 13 May 1997 23:53:19 GMT, desmith@telalink.net (Doug Smith)
wrote:
>why does exceeding 100%
>negative modulation cause so much more splatter than exceeding 100%
>positive?

It doesn't UNLESS you are deriving you modulation from a
voltage-modulated amplifier. In that case, you drive the amplifier to
cut off and hold it there for the period of over modulation. It isn't
the over modulation that makes for wide band sideband, it's the sharp
corners when the amplifier starts and stops cutting off the carrier
that makes splatter.

Now, technically--and this is a point that separates the men from the
boys-- you can never exceed 100% modulation, the point of carrier cut
off. No matter how negative you driver the anode (or screen or grid)
of a voltage-modulated amplifier you never get less than nothing.
And, at that point, the carrier is indeed cut off. However, in the
case of a voltage multiplier (like a 1496), when you exceed the point
of carrier cut off (100% negative modulation) you start increasing the
output voltage again. The carrier never disappears! The only
difference is that the audio energy in the area of "over modulation"
is out of phase with the input voltage.

Right you are ... forgotten already ...

>
> P.S.
>
> It is spelled "renaisance" yeah, yeah I know, why learn to spell when
> spell checkers are the current technology?

Actually ... I don't exactly have a spelling problem ... it's more that I
have
a problem with fine motor coordination and sensation in my hands and
fingers as a result of a spinal chord injury ...

Note, I'm not claiming to be the national spelling bee champ or anything,
just pointing out that sometimes my fingers trip all over themselves and
don't do exactly what I told them to do (sometimes they hit the right keys,
but in the wrong order, sometimes they miss a key or two, and sometimes
they hit adjacent keys)

Prior to the injury, I could type a solid 60wpm ... now I can hardly do
35-40
and that's seldom 100% error free ... I have to either slow *way* down or
use
a spell-checker to find the blunders ...

I am loath to invest a lot of extra time in chit-chat here, so I haven't
been
inclined to slow down to a snail's pace, and my newsreader doesn't
have a spell-checker ... so I guess you'll have to learn to live with my
imprefections as I have ...

73,
Carl - wa6vse
wa6vse@fast.net

p.s. If you doubt the veracity of my "excuse", I'd be quite happy to send
you a GIF or JPEG of the MRI from the neurosurgeon's letter to my primary
physician, clearly showing the spinal chord compression at C5-6 ...

5075. NEW DIY PCB PROTO TECH.- Printing direct on metal foil?!

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-15 00:00:00 UTC
From: stephens@enteract.com
Message-ID: <5le8ul$8vv@thorgal.et.tudelft.nl>
Source record: 94004
Cross-posted to: sci.electronics.misc,alt.comp.hardware.homebuilt,rec.radio.amateur.homebrew,sci.electronics.design

I've been reading a some threads on these newsgroups on toner transfer for fine pitch SMT and printing on metal foil. I tried it in my Epson Action Laser II, and it worked good!

Getting a SMOOTH piece of Al (Aluminum) foil, I folded it over a piece of paper and fed it into the manual paper feed slot. I took care that no wrinkles would scratch the drum! The transfer and fusing worked great! Unlike others results (dirty foil maybe?) the toner did not rub off. Inspite of the fact that, logicaly, it shouldn't work.

The significance of this is:
1. Print a reverse circuit image (toner around trace) on the foil.

2. Copper plate the aluminum foil. Very cheap, fast & simple (if not dirty)

3.With adhesive, glue the foil to a substrate. No doubt the hard part. I'm thinking of perfboard (I hate drilling!) Mylar (MULTILAYER BOARDS!!! Tooo coool!) or shitty old G10.

4. Etch the aluminum off, resulting in copper traces remaing behind.

No more expensive Mylar sheets & half transfered ironed toner. But best yet, by using multiple sheets, you might be able to do decent multi-layer boards. Via's would be made by punching holes before laminating the foil to the plastic. Copper traces extend over the hole, which would get filled with solder paste. I can't wait to try it!

But don't blame me if you mess up your toner drum, I bet Al foil will scratch it up real good. And a neg. image will use lots of toner. But should still be far cheaper, easier, and more powerfull than current iron on crap, which never worked well for me.

>
> 73's de Paul G7SPV

They're in my Mouser catalog (whether Toko or no, I don't know) --
stock no. 24TR218, $2.98 in quantities of 1-9. Mounting screws also available.

This is catalog no. 589 (Feb-April '97), so it may be possible they aren't
available. Anybody with a more recent catalog handy can confirm this.

Too bad for you -- Export orders minimum order $100 or $25 fee. (This
sucks, because Maplin didn't have anything this exorbitant when I ordered
from them!)

But if you're desperate -- export order fax number 817-483-0931

These are indeed handy parts -- they're part of a few tunable HF front-end
receiver filters, and my QRP Z-match antenna tuner.

RedHat is pathetically easy to set up; however, I would not advocate
dumping a perfectly good Slackware distribution to run the RedHat.
Slackware's rc files, bootup scripts, and config files are much better
kept than RedHat's, which, in my opinion, are needlessly scattered
into too many subdirectories.

I have nothing against the PNP or blue line stuff at all. It is a pretty
good product, it works well, is not terribly expensive for what you get,
and is easily available through the back of magazines. I have used it
with success in the past, but reverted to another method that I was using
over 10 years ago.

The method I have been using involves a clay-coated (zinc oxide) paper.
This type of paper is commonly used for thermal-wax transfer printers,
and some ink-jet printers. Since I work for a color printer group,
we have lots of this stuff around. The basic process is the same as
the PNP stuff, except you can fuse it to the copper much longer.
As long as you don't burn the paper, you are probably ok. Don't try to
pull the paper off after it has fused, but instead, soak in hot water
(the hot water doesn't affect the laser toner at all). After 20 minutes
(more or less) you can rub the paper off with your thumb. The only
thing left is the laser toner, and a little zinc oxide coating. The
zinc oxide will bubble a little when you first put it in the etchant,
but clears up pretty quick.
To get the stubborn spots off, use a small brush with the bristles cut
short (acid brush or 1/2" paint brush works best). After a little
practice, the results I have had are better than the PNP stuff, and the
cost of the paper is around 10 cents or less. I have used this method
for single side, double side, and surface mount boards with trace widths
down to 4 mil. I use a Tee-Shirt press to laminate the paper to the copper.
I also clean the copper with dutch cleanser, then rinse with tap water,
with a final wash of rubbing alcohol. Do not touch the board, the oils
in your hand can cause adhesion problems.

When chosing a paper, look for a smooth surface, and drag a penny across
it. If the penny leaves a colored mark, then you have a coated paper.

OK, now the disclaimer: I work for Tektronix, we sell a paper for our
Phaser 200 series printers. If you were to buy the paper from us, we
would make a profit from it. I get no benefit from it other than I work
for the company that would make the profit (and the satisfaction of helping
fellow Hams and hobbiests). Other papers are available at your local
office supply store, and of course the PNP stuff (which works pretty well,
but I never seem to have enough around when I need it).
I have not tried all of the papers available since I have one that works
well already, but some of them are likely to work based on the above criteria.

I think I'm gonna have to do a web page on this to spread around what
I've learned, and gather more information on home circuit board prototyping.
The opinions expressed do not necessarily reflect the opinions of my
employer. The opinions above are mine only.

You're kidding, right? Yeah, you *must* be! No one would state that in all seriousness.

> Your argument is the same as "Why learn to add and subtract? calculators
> are less than 5 dollars, why learn to read, everyone has a TV"

It can be argued that knowing how to add and subtract, and read, is somewhat of a necessity in order to be able to live in today's society. Knowing CW certainly isn't. Neither does knowing the code make one a "good amateur radio operator" -- listen in to the crap on 75m phone once in a while for evidence of this, only "know coders" there! CW is but *one* mode of operation, and one mode whose use is declining the world over because better modes are taking over. It makes no sense whatsoever to judge an applicant's ability to contribute to the Amateur Service, via their technological know-how, or other people-oriented service, based soley on his/her ability to use one particular (outdated) mode!

Try a tool supplier such as Rutland tool. They have a 10x,30x stereo
scope for $370. It has a swivel head and some other nice features.
It is hard to find used microscopes that are reasonably priced. You
might find a cheap scope,. and have to pay a furtune for eyepieces.

I present here my two most recent software which I hope they interest you.
they are progammed by Turbo C++ and run under Windows(3.11 and 95).
here is a short description of these two software.

1-Robot Spy 1.0
at my knowledge, this software is the first and the unique of its kind.
This software allow you to spy your friends who are on the net at the same time
of you, it permits to see exactly what they do on their screen, pixel by pixel,
anywhere, in the world, at the condition they are connected to the internet.
how does-it work?
it's simple, you send a file to the person you want to spy telling to him it's a
game or everythings else, the objectif is this person run the file. from this time,
a batch file is installed on his computor, and everytime this person use internet,
this batch connects him secretly on our server.
on your side, you , after the installation of the other part of the software every time
you want, you can connect on our server with your password and have the list of all the
persons who received your batch and who are connected at this time.
the only thing you have to do is to click on the name of the person you want to spy.
a window opens containing exactly the screen of the person spied, you can have
ten pictures per second with 256 colors, if you switch to balck and white mode you can
onbtain a real time sequence, approximatly 30 pictures by second.

Robot Mailer 1.1
The message you are reading presently is sent to more then 20,000 newsgroups with
this software. This program automates FreeAgent, and reach with a connection of 28,8 Kbauds
5,000 news per hours. It can also find a maximum of 50,000 e-mail adresses from internet
and
send a message in 4 or 5 hours. You can obtain with this sofware the most powerful tool of
mass transmittion on the internet.

Robot Spy 1.0.................20 US$
Robot Mailer 1.1.............20 US$
Both.............................30 US$

I'm sorry i can't accept credit card, but you can send an international money order to:

Ben Hedi Nassef
1481 Ste-Catherine est #7
Montreal, PQ, H2L-2H9
Canada

Don't forget to include your e-mail on a paper, you receice the software ordered in your
e-mail the day we receive the money order.

Welcome to the joys of operating and maintaining a repeater...
Where else do you get to play with a system that has a 175 dB
of dynamic range.

I wouldn't be suprised if you could get the 'cracklies' by rubbing
two peices of metal 20 feet away from the antenna with no
connections to the repeater system at all. In fact, a friend of
mine had to go lubricate his neighbors attic fan regularly to keep
his repeater cracklie-free!!

I wouldn't be that quick to blame the 'cracklies' on grounding.
Remember that anytime you have two dis-similar metals touching
each other, you have the potential for galvanic corrosion and an

opportunity for introducing a non-linearity (a crude diode) into the system. Changing the non-linearity by changing the pressure on it or by moving the surfaces causes de-sense. I suspect that the non-linearity is modulated at 600 KHz when wiggled but am unable to make any measurements to confirm this.

Since I can't afford a 'real' repeater antenna, mine comes down every year for cleaning. It is completely disassembled, cleaned, all joints are lubricated, and then it is reassembled. It had a steel mast for a week but we never could make that work well. An aluminum mast fixed everything up (the antenna is aluminum).

As for a definition of a "good connection", for me that meant absolutely corrosion free, lubricated, and with both conductors of the same metalurgy... and remember a connection is made any time two metal objects touch each other.

I'd recommend the 'divide and conquer' strategy.

As I undwerstand it, you say the only thing(s) different were the
2sc's and the absent ground plane.

The second poster said he had a ground plane but don't worry
about it. WHY NOT? It seems one of the prime suspects.

The proper xtors should be simpler, but the graound plane had a
reason and you may have discovered it.

Maybe to prevent a self-parasitic=suppression?

Good luck

Apparently, so is getting this thread to stick to my original subject,
I say again, I do not need your approval, your confidence or even
your diluted snidery.

WHAT I DO NEED IS ADVICE HOW TO KEEP SOMEONE FROM
HAVING THE IDEA THAT IDEAS ARE FREE, and never mind if
the poor sod that developed it spent all his money and half his life
in the process.

I do not refer to myself as that poor sod, because I can criticise my
own idedas until I bring them into working order. I just cannot sell
them thereafter, and never yet have I successfully trusted anyone
with the basis of the idea.

By the time I was 16, I knew better, and many is the time someone
thought they hadit all and said some version of "don't call us" as
they went on their merry way, only to find later that they hadn't got
the whole thing after all.

There is some method of assuring that the process is more or less
safe, and that is what I need.

Se, all the people who want me to *prove* that what I "claim" is true
can spend their time on something more profitable.

All i asked for was advice how to protect the stuff.

Actually the radio thing is minor, I have more and bigger stuff, and
can't see how to protect it either.

Any suggestions anyone (except naysayers)?

Thank you in advance.

Lou Hinshaw
tulsa OK USA,

Plain and simple, consult a competent pattent attorney or patent agent,
who is registered to practice before the US Patent Office (a list of such
is available on the US Patent and Trademark Office at
<http://www.uspto,gov>

If you truly have confidence in the value of your ideas and that they are
new,
novel, and useful, then you need to seek legal protection in the form of
patent
rights, if that's possible.

That's the plain and simple answer ...

5096. ALINCO EC10 LPD radio

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-16 00:00:00 UTC
From: Jochen Ziegler <jochenzi@hpbbn.bbn.hp.com>
Message-ID: <337C5E68.5592@hpbbn.bbn.hp.com>
Source record: 94025

I have bought a LPD radio from ALINCO. The name is EC10.
The low power device has 10mW output power.

Let me know, how to change the output power from 10mW to 50 or 400mW.
Is the frequency after the change the same?

Jochen

Greetings!

In article <5lgg1b$nrm@camel4.mindspring.com>, aruder@pipeline.com (Lou or Annette Hinshaw) writes:

>There is some method of assuring that the process is more or less
>safe, and that is what I need.

Documentation, and your own analysis and how the idea can improve a product, or replace a product, or a concept that has not been expressed that provides a means to improve the quality of life - or a physical device that utilizes a unique process, either by function or designs, in it's operation, neverbefore considered.

>Se, all the people who want me to *prove* that what I "claim" is true
>can spend their time on something more profitable.

You don't need to tell them your idea, only what the idea can do.

An Attorney may be in order...

>All i asked for was advice how to protect the stuff.
>
>Actually the radio thing is minor, I have more and bigger stuff, and
>can't see how to protect it either.
>
>Any suggestions anyone (except naysayers)?

Documentation! Documentation! Documentation!

Contact an Attorney, discuss the terms in which you'd like for him to witness an idea - follow his instructions - it may go something like this...if they are different [instructions] follow them exclusively.

Describe the idea...date it and sign it. Make a written statement.

Put in an envelope and send it to yourself, or to him, or both - it'll have a
postmark of the actual date of the postal system, acknowleging that this envelope existed at some time, somewhere.

It's up to you now, to find an Attorney, and or Nortary Public to witness the envelope being opened. They will have to view the contents of the envelope and assure that the envelope was sealed before it was presented.

The idea inside the envelope, if you have an Attorney present - can reseal the envelope as a "confiscation" clause. It can remain in his possession, so copies are needed. As a part of the witnessing that occurs, they should

be able to supply a certified means of acknowledgement and/or copies. However, when discussing "copies", it's usually frowned upon. Usually a receipt process occurs.

It is now your responsibility to provide the attorney with the details on which you wish to apply for a patent, or collateral to develop a prototype, based upon your idea.

If a prototype was developed at your own expense - this can be presented as workable evidence of your idea - then a patent can be easily applied for.
A search within the Patent database is going to take some time - however you have some protection during the search time, due to the witness and postage cancellation stamp. This occurs "up front" with a witness.

It is up to your Attorney to decide on workable means to develop collateral
or applying for a patent - this is the most expensive, and time consuming part of the process.

Good luck, some trust, as said earlier - is needed.

Tony-

Communications Specialists make encoders and decoders. I don't know if the decoder chip is available alone.

Their products are carried by Amateur Electronics Supply and others. I don't know if they have a web page.

FOR SALE
CSI CS-900 VOX SIMPLEX (or repeater) AUTO TELEPHONE PATCH (Interconnect). Makes your HT like a Cell Phone. Works extremely well. Dual-bander not needed at base. 90 speed dials, two level safety codes. Built in programable keypad and volume adjustments. Needs only a mic and audio out conection on any base radio (or HT). Phone line plugs right into the back. Multiple and flexible options like notification if someone is on the base phone, and when they are done. Range over 15 miles simplex (30 mile across circle) on 2m band. More simplex range with nice base antenna, more height or an amplifier. Ever more range through a repeater. Just tune the rig to a wide coverage repeater (A club could run this patch from a home). Connects to any rig so use it with a LOW COST spare 2m (220 or whatever). Easy volume adjustments and BUILT-IN keypad. Of course CW ID makes it legal. Dispach and selective calling too. It's your choice, YOU are the control operator. Plus, a long list of other professional features. With a cross-banding rig in your car, you can go all over town making AND RECIEVING calls on simplex with your HT on low power 440! Set it to ringout, send DTMF (touch tone) code or use a silent PL tone, sent to your HT. Imaculate $299

5105. SOME INTERESTING QUESTIONS

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-17 00:00:00 UTC
From: jorgegc@mundivia.es
Message-ID: <337e612a.149612@noticias.mundivia.es>
Source record: 94034
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew

Dear friends, I own a ICOM 706.
I would like any of you to send me all information, mods, improvements, and so with the 706. I would like to know also about the interfaces and programs for the 706 and the PC.
I am also very worried about these questions about blowing the 2 metre section up if you have the HF aerial very close to the 2 metre one. I have a vertical antenna for 144 in the same post support than a windom for 80-10metres. Is it any dangerous?. What is the proper distance?
By the way in my building there is a lightning arrestor (pararrayos) post at only 2 metres from my antennas support. I have always thought that this could be some dangerous though Valencia is not a very stormy city. Anyway, some friends have told me that it is the same dangerous as it would be 50 metres away as a lightning has an action radius of about 150 metres, even a local ham told me to put my windom aerial up to the lightning arrestor mast which is 5 or 6 metres higher than my antenna post. He said is the same danger in the lighning post than only two metres away. What can you tell about all this?.
Will it be enough just swithching off the antenna plugs of the transceiver in case of a storm?.

Another question is, What is the proper high for a HF vertical (WARC Bands 18 & 24Mhz) above the roof of a 14 floor building? Mine is only at 1.5 metres from the roof and works OK, but many often is beated by the windom one which is only 4 metres from the roof. This is strange for me as I have always read that a vertical is always better than a dipole if that one is not at least at wave over the ground. For this theory, my vertical should be better because the dipole windom is only at 4 metres over the ground (the roof of my building), but in many cases the dipole overbeat the vertical. Can anyone explain this to me? I have read many E mail messages of hams talking about the pros and cons of verticals and dipoles, but nothing is clear yet. What is the real truth? Is really any real truth?

Thank you.

Content-Disposition: inline; filename="FT-9012.TXT"

PROCESSOR LEVEL CONTROL is a perhaps just a JOKE, no control range is achieved.
Replace Q207 with a P-channel FET type J177, 2N5462 will work, too.
Change R229 to 10K.
R225 is increased to 330 ohm - LA8AK 1989

NOISE BLANKER
The noise blanker is not the worst I have tried!
Some time ago I modified the noise blanker in FT-7, and the solution to FT-7
is found in FT-7B! Unfortunately it seems that although the persons who made
the FT-7B made a good job in this respect, they may not be engaged to work
with other equipments so often.....
On PB-1995 FILTER UNIT (PB 1716 in FT-901) C328 was increased by 0.1uF
Result was 1 S-unit reading (S9+20 without noise blanker).
With 0.22uF, there was no reading at all, and the noise could hardly be
heard. LA8AK - 1989

FT-902 IMPROVEMENTS (2)

PUSHBUTTONS.
After some tears in use the tend to be difficult to operate, with a little
spray, they will be as new. It is in particular a spring seen from behind the
front cover that must be operating easy. (LA8AK)

10M FM
Modulation seems to be for 2M standard, 25KHz channel spacing standard.
On 10M is 10KHz standard, and a smaller filter should be used.

(A narrower filter should be used) - LA8AK

RECEIVER INCREMENTAL TUNING (CLARIFIER) - FIRST TRIAL (LA8AK 1989)
Requirements
HF SSB +/- 5KHz
HF CW +/- 1KHz
2M CW +/- 2KHz
2M CWMS +/-5KHz
2M/70CM SSB +/-5KHz
2M AURORA +/-5KHz
70CM AURORA +/-10KHz
I have chosen to use +/- 1.5KHz approx
VR06 is overcoupled with 1K5, VR06 in my RIG is 5K, in other FT-902's I am informed they have another value, so the modification must be different.
VR01 (470 ohm) is re-adjusted, in my RIG the nominal voltage is 2.6V

CARRIER LEVEL CONTROL- LA8AK 1989
A 5K potmeter is used, but the effective variable value is only 1K, it means that 80% of the rotation makes no change in RF output level.
To improve this, connect a 1K2 resistor on PB-1994 (NB-UNIT) pin 5 to ground.

AUDIO QUALITY - LA8AK - 1988
As manufactured the quality is terrible, I could not use the receiver made me headache! Bass-response. Solution to the problem is found in FT-7, same IC is used here. C511 - AF to AF-power amplifier is changed to 47nF, and quality is now perfect!!

FSK - LA8AK-1988
DC level to FSK input on the RIG is low, and the input transistor may be damaged. Only 1.5-2V dependent on series of production on PB-1706 carrier unit.
Loosen base of Q701, insert a 4K7 resistor between PCB and the transistor.
Now the noise margin is better and TTL level can be used if you want.

IMPROVING FT-902-DM (3)

BETTER BIAS CIRCUIT - LA8AK-1989
Connect a diode - 1N4007 - between (PB-1708 RECT A UNIT- NO 10) pin 5 and C11, cathode to C11. Will help for as in valve.
Connect a 100K resistor between C11 and R12 (over one part of potentiometer VR01 10K) This will help to protect valves when bad contact in potmeter.
...I have bad contact in keyboard...read...gas in valves
Although not shown on circuit diagram a diode, similar to 1N4148 is connected in series with screen grid voltage to valves. In series with the RF-choke.
Connect a 10K resistor over this diode, PA printed board.
Cconnect one varistor SIEMENS S14K150 from each screen grid connections to ground, to help in case of flash over, to protect the opposite valve and the power supply, which is not particular over rated.

KEYING - LA8AK-1989
As original the keying sounds bad on a good ear.
Connect a 0u47 capacitor on PB-1717 RECT-C pin 16 to ground, MOUNTED ON THE

printed circuit board.
Connect as follows on PB-1708 RECT-A UNIT
KEY PIN 2

PIN 2 -!-----100K-!-----------0.33uF-------I GROUND
! ! 100V capacitor
!-->I------!
1N4007 cathode

The diodes mentioned here 1N4007, the reason to use 1N4007 (1N4002) is not for current (1N4148 is good enough in this respect), but this rectifier type will be a bad RF rectifier, and that is important.
The reason to use this device capacitor, is that charge and decharge current is different, so to make same start and fall times for the keying, a diode circuit must be used.
Reports on the air is good. I operate quite a bit on CW on HF/VHF/UHF

PTT
Connect a diode in series with PTT relay. Otherwise the RIG will activate a transverter when switched off. - LA8AK-1989

MIKE
I changed the mike connection to the KENWOOD connection, so that I can use same mikes for different RIGS - LA8AK-1989
Later I used only YAESU mikes for all my RIGS! Even KENWOOD.

AUDIO OUTPUT - LA8AK-1989
An unused part of LM324N/MC3403P on PB-1705 can be used as buffer for independent audio output for packet radio, RTTY, CW-METEORSCATTER.
An unused cable goes from AF-board MJ6 to VOX MJ-7, since I do not use tone output of transceiver from sidetone osc. The connection to the rear can be used, but it is too difficult to describe it here.

Independent line output for FT-901/FT-902
PCB: PB-1705 AF, PB-1846 VOX

used for AF line O/P buffer

PB-1705<MJ6 PIN 16> screened cable<MJ7 PIN 7-VOX>-- 1K*-----J17 TONE OUT
SCREENED CABLE 'REAR'
Notes:

**R504 position used for 1nF capacitor, RF decoupling
* 1K original resistor mounted to J17 is 4K7, leave it or change it, depend upon your interest, output level is 0.5V P-to-Peak
This modification uses an unused part of the IC 'Q504'. Some components are marked on the PCB. Some of this existing components use some of these points, remove these first, and connect then into the air above the PCB.
R533 10K goes between pin 2 and 1
The 22nF capacitor must find a place between emitter of R513 and the IC. A link must be inserted between C520 and the 2K2 resistor on the output.
(R52 is losen in one end to do this modification) -LA8AK 1990

FT-902: BIAS CIRCUIT RECT - LA8AK 1990

Perhaps this circuit diagram is better to understand...

```
'-100V'
I
R12
I----NEW 100K-------------I-------I<----------I
I I NEW 1N4002 I
END1 I I----'BIAS'
POT.METER I I
CENTER--------------I----R05------------I
VR01
END2
I
I
R09
I-------KEY(2)
```

The two added components are: 100K 0.25 or 0.5W +/-10% resistor
1N4002/1N4007/BY100 rectifier diode
The diode should help to protect the valve if positive ionization occurs in the valve/grid circuit - it might reduce bias voltage. This was mentioned in RADIO COMMUNICATION, Technical Topics about 1972-1974...sometime
The resistor as connected are always FB to use. I used this also for some british AJAX transmitters used for coast radio stations to save 4-400 valves and avoid break-down.

FT-902 CALIBRATOR PB-1846 - LA8AK 1990

Proposed change to avoid intermodulation distortions as described for FT-7 and FT-250.

```

MARK B+---47K--------B BC547/BC548/BC238/2N3904/MPS3394
(4) E TUN (NPN general purpose transistor)
I
GND
Connect: 47K from collector Q613 (marked Q6) to GND
47K from collector Q614 to GND point of printed circuit board

PB-1846 VOX/MARK UNIT -(LA8AK-1990)
Also: refer to earlier note: separate AF line output, R652 (pin7) is lifted up in one end, since pin 7 of edge connector is used for this line-output circuit.

FT-902: PB-1707B FM UNIT -(LA8AK-1990)

Nominal TX IF voltage is 60mV. Carrier from FM board is far too high, but there is used 'some funny practice with trimming capacitors' in several japanese RIGS to adjust levels. This should be avoided whenever possible, because unstability may occur because the different stages do not see a real & low impedance. Diode gates are much better policy!
On FM-UNIT PB-1707B I removed TC903 and replaced it by a trimpot 2K2. In about same position. The input from TC903 goes to the wiper. One end is grounded, the other is "output"...to diode gate.

I----C963--I--->I------PIN-4--60mV FM carrier
I I 1N4148/BA182
UPPER END I
FROM---CENTER 2K2 2K2
T903 LOWER END I------10nF----GND
I I
GND 2K2
<FM level> I----PIN 4 FM CARRIER SWITCH

FM out is pin 14 (not pin 4!!)
Under the socket must be connected a 4K7 resistor to ground or better at input to NB board <pin 13> on the junction of different cables which also comes from FM-UNIT <pin14>
The obscure trimmer capacitor connected between <CARRIER PB-1706A> and <NB pin 13> is removed, wires on each side are joined.
A similar diode switch is also mounted on the output from PB-1706A.
Nominal IF voltage for TX is 6mMV, however with a defective RF speech clipper <so called speech processor> or signal from FM-UNIT adjusted far too high, it may reach 400mV.

Well, this is some of the modifications I have made, personally I think this RIG is now splendid! I have used over 20 different RIGS/receivers during 1960-1989

FT 902: DOES AMGC WORK? - LA8AK 1990

I just wonder if anybody has considered the 'AMGC' function.
I believe it is thought to be used to reduce the signal level into SSB modulator when background is noisy.
However, my experience from similar use of transistor as Q709 (2SC1815) on

PB-1706A CARRIER UNIT (see NB UNIT - Q207 2SC1815) is that it does not work
at all..., and how can it then work in another similar circuit?
I would suppose that a vmos fet would have been better.
The actual circuit is:
---FROM NORMAL MIKE AMP---TO BALANCED MODULATOR
I
C753 33uF
I
C Q709 2SC1815
FROM MC14011/A--56K---I--------B
PIN 3 PULSE/FUNCTION 22uF E
GND
Proposed change (not tried):
BASE TO GATE, COLLECTOR TO DRAIN

+8V-------10K-----I------------I---- TO SOURCE BF245
22K POTMETER 47uF
I I
GND GND

AMGC function switch was later used to select between SSB/CW filter for
CW reception. LA8AK-1992

FT-301/FT901/FT902 RF-CLIPPER(SPEECH PROCESSOR) - ONCE MORE

After having received some requests for this circuit, here it is once more
same clipper is in FT-301.

I-->I--I diodes 1N4148/1N914/1N916
I I
I--I<--I
I I
PIN 4 PIN 5 Q206 TA7060P (SSB limiter amplifier, which does not limit voice)

Gain control/processor level (not processor level, he cant be so stupid!)
Change R229 to 10K
Change transistor to P-channel FET 2N5462 will work but it could have worked
better, poor 6dB-8dB, but it is a waste improvement to the original. Some
effect is lost in ALC operation.
I
D
---------G
I S
C224 I
I--------I--GND

Perhaps it is possible to use an N-channel FET for better operation and more
easily available transistor. Proposal is BF245C. N-channel...
I
C223
I
D

GND-----G

I----100uH---I-------I----PIN 10 EDGE CONNECTOR
I I I
tantalum 1uF C224 R229
I------------I I CONNECTED AS BEFORE
IGND GND I

R229 IS 2K2....10K

In the first circuit diagram 'D' is connected to C223 as original (collector)

------PB-1994----- will also work for FT-901

FT-902(2) RF SPEECH PROCESSOR

It is necessary to invert the function of the 'processor level' potmeter
The center connection is connected to the opposite end-terminal (LA8AK)

FT-902: REDUCING TRANSVERTER RF DRIVE (1989 LA8AK)

It is very simple, and I have used this for all my previous RIG's:
FT-250 (200), FL-DX-500, HX-20, FT-101B, DRAKE TR-4, TRIO TS-500

Instead of a 10pF capacitor from PA-GRID circuit I use a capacitor and
resistor

------2p2----1K------TRANSVERT OUTPUT
Output will now be maximum 10mW, perhaps less. So 4p7 may be a better
capacitor value. But I use my MICROWAVE MODULE transverter with maximum
sensitivity for TX-drive

FT-902DM, CW-WIDE/2.4KHz MOD.

Here is a list - as I remember it to install a CW-MS keying circuit as
described or a similar unit for proper keying with transverters.
PB-1706A Carrier pin 8 ----CW/AM/FSK +12V---Connect to CW MS board +12V
PB-1706A Connect on the board: pin 11-->I---pin 10 1N4148/1N4002
PB 1705A AF pin 6 is used for +AM which enables the keying on CW MS board
Connect a wire from key-jack to key input on CW MS board PB-1994/1703C NB.
Connect a resistor on plug pin 13--4K7-- pin 12
Remove all the wires for the built in keyer in the transceiver, even the
wires to and from the switch/potentiometer on the front.
FILTER PB-1995/1716
SSB pin 13---------I<---I------- C318
AM pin 14---------I<---I R315,R317,L308 (junction)
If you wish to have variable bandwidth control for 'CW WIDE' (I do not see
the point) remove the wire going to 'IF' pin 16 from S2C, and connect a new
wire from 'FM' pin 4 to 'IF' pin 16, this wire is only used to remove the
variable bandwidth function for FM, when voltage on it - function is
disabled, the IF board is in FM-mode only used for S-Meter function.

The modes referred to function switch as modified
1 LSB LSB (SSB)

2 USB USB (SSB)
3 CW CW NARROW (USB RX) CW NARROW (USB RX)
4 FSK (CW NARROW FILTER/LSB) FSK (as before/LSB)
5 AM CW-WIDE, USB RX 2.4KHz BW
6 FM FM
All these modification has been made without any impossible changes at the
mode switch, I looked at it and resigned !!
One problem remains, the output PWR on HF (not VHF with transverter) will be
lower for CW wide than for CW/SSB.
A 15K resistor is inserted in series with the screengrid supply voltage at
RECT-C. If you are a good operator, this resistor can be removed, otherwise
the mode switch should be rewired at position AM, S2A-front wafer.
S.G +-I-------SSB/CW---0
I S2A--------I-----------160/15M---0
I---15K----------0 I BANDSW.--- SCREENGRID
RECT-C I--2K2------10M-------0
A smaller reduction in screengrid voltage is also introduced for 10M

The next modification is receiver incremental tunning:
+/- 5KHz for SSB/CW-NARROW/FM
+/- 1.5KHz for FSK/CW-NARROW (should read CW-WIDE above)
For this modification I would use a dual op-amp and a J177 P-channel FET.
This will be shown later
CWMS KEYING BOARD WAS LATER ABANDOMED BECAUSE OF AURORA SOUND ON SIGNAL
RECEIVED- THE FAULT WAS NEVER TRACED. SEE NOTE ABOUT AMGC SWITCH - LA8AK

FT-902. 'CLARIFIER RANGE' SELECTED BY MODE.. -<< LA8AK >>-

Selected clarifier (Receiver Incremental Tuning) range for different mode
I have made a suggestion for the range meeded dependent upon different mode:
LSB/USB/CW-WIDE/FM/(AM) +/-5 kHz RIT
FSK/CW-NARROW +/-1.5kHz RIT range
In fact the result using simple components with this RIG is:
Narrow range: +/- 1.4KHz, for mode selector position CW (marrow) and FSK
Normal range: +/- 4.8KHz, for other selector positions
The circuit uses an MC3458P1 (LM358) dual op amp and a J177 P-channel FET.

LA8AK RX/TX CLARIFIER
SELECT PUSHBUTTONS
This circuit shows the solution for YAESU FT-901/902DM
However, the idea may be applied to most available transceivers up to the
newest versions, most of the circuit details are similar or easy to see how
to insert this circuit.
The reference potmeter is the small trimming potmeter used to adjust the
RIT/clarifier center frequency.
The orange wire from clarifier center is removed and connected to the output,
pin 1&2. A new wire is connected between the 10K resistor at the input to pin
5 (!!) and the center of the clarifier potmeter. <LA8AK>
```

COLLECTED BY HARRY..G0LHX @ GB7TJF #45.GBR.EU - NOVEMBER 1994

Hallo OM Jan-Martin,

I saw a message from you titled "FT-902: Improving
RX-MIXER.....". I own both a FT-901 and a FT-902. Some years ago
I changed RF unit of the FT-901 (PB-1702) by a FT-902 RF unit
(PB-2154). I can tell you it works fine! The only thing you
should be aware of is that the three connectors on top of the
module have changed position as follows:

```
position |FT-901 FT-902
---------+----------------
top |Red Yellow \
middle |Yellow Green } colour mark of
bottom |Green Red / the coaxial cable
```

If you make the right connections the PB-2154 works right away
in an FT-901. No further modifications necessary. <LA8AK>

A note from "The Antique Radio Collector" <<
http://members.aol.com/wrldradio/index.htm >>

Beginning this month, we are happy to announce our affiliation with "Amazon.com " We believe you will find our new book store offers one of the most comprehensive listings of books and tapes relating to the collecting of Antique Radios, Old Time Radio and Amateur Radio, and related subjects offered anywhere, many with discount pricing. Hopefully, we have now found a way to support our website so that we may continue to offer "free classified advertising" to collectors and maintain a site you'll find worth visiting often.

You should also know that all transactions made from the store are handled directly by Amazon.com, through their "Secure Server" service, for your protection over the Internet "and all orders and shipping are processed directly by Amazon Books".

So, when you need a resource book or just feel like reading a good book (or listening to OTR audio tapes), please visit us at:

http://members.aol.com/wrldradio/bookstore/bookstor.html

<< "Amazon.com Associates" list selected books in an editorial context that helps you choose the right books. We encourage you to visit "The Antique Radio Collector" often to see what new books they've selected for you.

<< Thank you for shopping with an "Amazon.com Associate".

<< Sincerely,

<< Jeff Bezos

Sounds like a parasitic oscillation might be causing excessive current drain, which eventually alters the characteristics of the circuit enough to keep it from amplifying the desired signal at all.

Pitfall 1: a 2SC2092 transistor was subbed for an MRF 472/476. The 2SC2092's NTE equivalent (don't have the original data sheet handy) is specified with an ft of 300 MHz, while the 472/476's equivalent is spec'ed at 150 MHz. If the same is true of the OEM parts, that could be a problem. When it comes to transistor ft, more is NOT always better -- in this case, it will make the circuit much more prone to parasitic oscillation at some unknown VHF frequency. With a ground plane, this would be unlikely to occur, but...

Pitfall 2: I wouldn't build a code-practice oscillator, much less any type of RF circuit, without a good ground plane. :-) Do yourself a favor and throw away every scrap of "perfboard" you own, and give it another try with dead-bug construction on bare copper-clad board.

Mark: Thanks for digging up the article. I've read it MANY times.
In fact it was Macleish's article that really got me thinking about
the physics of radio.

I liked the article and it helped me a lot. But it really doesn't
provide that gut level understanding that we've been talking about.

Like many authors on this subject, Ken doesn't really point out that
there are limits to our understanding of these matters. When you get
right down to it, no one really understands what an electron IS, what
charge IS, what the magnetic force IS. Also (as far as I can tell) no
one REALLY can understand or explain the particle-wave duality. Just
ask a someone to explain how particles are generated by your 20 meter
dipole!

I've found that in this search, you have to consult lots of books. No
one author seems to have it all. Many seem to have big pieces of the
puzzle, but stumble in other areas. For example, I found one British
author who did a great job describing almost all aspects of EM
radiation. But then he wrote that the magnetic field is just a
relativistic effect caused by the motion of charged particles. That
little statment cost me months of confusion. Finally some of the
Physicists over in the COMPUSERVE Science Forum pointed out that while
relativistic effects are there, magnetism cannot be considered as
JUST a relativistic effect.

Another point: Many of the texts discourage efforts at understanding
by telling layman that unless they can master the calculus of
Maxwell's equations, they can't possibly REALLY understand what is
going on. I disagree strongly with this statement. I've learned
enough calculus to have an inkling of what is going on in the
equations, but I think the basic lessons of Maxwell CAN be explained
without the math. And I suspect it is possible to really master the
math without really knowing (at gut level) what is going on.

As for Nahin's statment about QM and transistor theory, I went back to the books and found a number of texts that I've used have quite a bit of not-too-mathematical QM theory sprinkled in there.

Good luck in your search for the gut level understanding!

CB TO SIX METRES Part1 - The Introduction

By Shawn Baris ZR1EV
PO BOX 212
Brackenfell
7561
Republic of South Africa

Anyone is free to use the following information for private use on the provision that it is not used for commercial purposes . Permission is granted by the author , ZR1EV , to publish and or distribute all or part of the following on the condition that recognition is given to the author .In the case of it being used in a newsletter or magazine , a copy of the aforementioned should be sent to the above adress.

Having allways had an interest in "band 1" propagation , and being spurred by reports of TV signals from the old Crystal Palace transmitter on or around 45Mc being recieved regularly down here in Cape Town during the Seventies , It was particularly frustrating not to be able to operate on the 50Mc band . This band was for exclusive use by ZS-call holders and as you can see by my call , I hold a "VHF-only , no-code" ZR-call .
Things changed in 1981 , when it was announced that the six metre band will be opened up for holders of the ZR-call on the 1st of January 1982 . I was extatic ! But elation was soon followed by disapointment when it became apparent that there were very few rigs to be had , and the prices of those available were way above what I could afford .
I was given an ex-military rig by OM Dave , ZS1SG , but soon realised that if I was to really exploit the amazing fare of different propagation modes possible on six metres , I would have to use SSB/CW and have more power at hand , when it was needed . A transverter seemed to be the obvious choice at the time , and I proceeded to aquire an SSB/AM CB rig , with the idea to convert it for operation on the 10 metre band , which I would then use to drive a transverter I was still going to construct .
After the mod to the rig , (which worked extremely well) , I proceeded to experiment to find the best circuit for a transmit converter that would eventually form part of my prototype . At this point , I realised that the whole idea is not going to be all that simple . The local oscillator would have to have a frequency of 22 Mc . (22 + 28 = 50) . Unwanted products from the mixer would be (28 x 2 = 56) and (22 x 2 = 44) These unwanted products from the mixer i.e. 56- and 44 Mc are only 6 Mc away from the wanted output and were going to be very difficult to attenuate to the required -50dB (min) level required and to have a consistant clean output across 50-52 Mc would be asking quite a lot from the mixer and filter stages . To cover from 50-54 would paint an even bleaker picture and would involve switching bandpass filters to enable the unit to stay within minimum spec .

At this point , something else dawned on me . For the rig to operate on 28 Mc , the local oscillator would have to be on (28.000 + 10.695 = 38.695) . The 10.695 is the IF frequency used on the rig I had and the local oscillator is injected on the "high side" of the desired operating frequency . It now becomes clear that if the Local oscillator signal could be treated as if it would be injecting on the "low side" of the desired operating frequency , the new frequency (image of 28.000 , with 10.695 IF) would be 38.695 (LO) + 10.695(IF) = 49.390!
If the Local oscillator signal could now be made to go up to 39.305 (rig operating on 28.610) we now have (39.305 + 10.695 = 50.000!) . This forms the basis of the modifications to follow . I part2 , I will discuss the frequency synthesizer , and how to actually go about moving the rig up to round 28.600 , which will be the first step in the mod . Also , bypassing the inherent problems when using a 40 CB channel switch in any mod , albeit to 10M or to 6M . (5 "gaps" where the frequency "jumps" 20kHz and the sequencing problems round ch23-25 , and the nuisance of having to have a typed piece of paper stuck to the rig to tell you what channel=what frequency) The conversion is well worth the effort and I have already done dozens of these mods . The bugs in the early prototypes have been fixed and due to presure from the local guys , I have decided to "put pen to paper" and share what I found from years of experimenting and perfecting .
Hope you will be able to enjoy it as much as I have . Please let me have your comments and input .

CB TO SIX METRES Part3 - The PLL Frequency Synthesizer continued

By Shawn Baris ZR1EV
PO BOX 212
Brackenfell
7561
Republic of South Africa

Anyone is free to use the following information for private use on the provision that it is not used for commercial purposes . Permission is granted by the author , ZR1EV , to publish and or distribute all or part of the following on the condition that recognition is given to the author . In the case of it being used in a newsletter or magazine , a copy of the aforementioned should be sent to the above adress

In part2 , we had a brief look at the basic operation of the PLL frequency synthesizer (If you want a more detailed description , do drop me a line) and from that we can see how the channel frequency is generated . If now , for example , we change the binary input to the PLL chip to something else , say 234 , it would result in the phase detector generating an "error" , which will drive the VCO to the new frequency so that the loop will once again be in the locked state . As the VCO will now have moved 10kc , the resulting sum output will also have incremented by te same amount , resulting in the transceiver effectively having changed frequency by 10kc . This scheme is fine for changeing frequency round the design operating frequency of the radio , but to change "band" to a frequency more than 1MHz up , one has to watch out not to exceed the 3.5MHz maximum frequency input to the divide-by-N counter . It should be clear that the synthesizer frequency can be moved higher by changeing the 10.0525 Xtal to a new value. There should be no need to rush out and buy one , just have a look in your

"junkbox" for a Xtal with a fundamental frequency round 10.400 . After you have done the replacement the alignment is easy . Attach an RF voltmeter / 'scope / RF "sniffer" to test point3 (TP3) and , using the propper (!) trimming tool , adjust the core of T3 for max deflection . Then , connect a DC voltmeter to pin6 of the PLL02A chip (take care not to short any of the pins) and carefully adjust the core of the VCO "block" until you get a solid 5V in that pin . Flick the channel switch from CH1-CH40 while checking the voltage on pin6 of the PLL ic and confirm that it stays 5V . The PLL is now locked . Connect the RF Voltmeter/'scope/sniffer to pin4 of IC3 (C3001/TA7310P) and adjust T1 and T2 for maximum deflection on Channel20 . Remember that the rig will not transmit if the PLL is not locked . When pin6 of the PLL chip falls below 5V , it "switches off" Q7 in the transmitter predriver stage , rendering the transmitter inoperative . Set the rig in the transmit mode and realign the set as per the manual for

maximum output . Rig should now be transmitting somewhere around 28.600 and the exact frequency can be checked with a frequency counter .(Please remember to have the rig in the AM mode for measuring the frequency - sounds obvious , but easy to forget in the heat of the moment)
You will now most probably be on a somewhat "wierd" frequency like 28.7842 or suchlike . (At no time touch the 10.692MHz oscillator trimming caps , CT4 and CT5 - I will explain their function later . They should not be touched at all if your rig was operating 100 percent on 27Mc) . The easiest way to go about the following procedure , is to have an HF reciever on hand with SSB fascilities . In the previous example , say 28.7842 , tune your reciever to either 28.780 or 28.790(preffered) . Key up the rig again (in AM mode) and adjust CT1 for a zero beat on your reciever (Which should be set to USB) The rig should be keyed into a "Dummy load".
Now set your reciever to LSB and do likewise on your rig and while modulating , adjust CT2 for a natural sounding voice on your reciever . If necissary, experiment with the values of C20 and C21 to get the rig spot on frequency . You should get no less than 4W on AM and 12W on SSB after the mod , and if you want , you can realign the reciever strip now as well using an adjustable signal generator and use the set as a 10M rig , or get ready to continue the mod up to six metres . Good luck .

CB TO SIX METRES Part4 - The Reciever Section

By Shawn Baris ZR1EV
PO BOX 212
Brackenfell
7561
Republic of South Africa

Anyone is free to use the following information for private use on the provision that it is not used for commercial purposes . Permission is granted by the author , ZR1EV , to publish and or distribute all or part of the following on the condition that recognition is given to the author . In the case of it being used in a newsletter or magazine , a copy of the aforementioned should be sent to the above adress.

Now that the rig has been converted to 10 meters and it has been thoroughly tested there , we can proceed with the conversion to 50Mc . You may by now have noticed that the chassis of the rig is isolated from the earth-plane on the printed circuit board itself . This was done to enable the rig to be installed in either a positive- or negative earth vehicle .
The chassis must be at RF earth though , as the antenna socket must "see" the earth on the PCB . This is where a lot of "conversions" fall short in performance . So what needs to be done first is to replace all the disk ceramic capacitors that connect earth and ground together . All round the PCB where it is screwed to the metal chassis , you will see them . Don't forget the two caps on the DC connector ! Change all the capacitors with a value of 0.047�F (47nF) to 0.022�F (22nF) .
Now for the reciever section . Change C100 (33pF) to 18pF and remove T7 . Carefully disassemble T7 so you can get to the windings . Hold the coil former upright (pins facing down and the side with the 3 pins facing you) . CAREFULLY liberate the wire from the righthand pin and unwind the existing windings , taking care not to break the delicate strand . You'll see that the former has 4 "ribs" to hold the winding . Leave the wire attached to the leftmost pin and proceed to first wind 4 turns onto the second "rib" from the top in a clockwise direction . The "ribs" have a gap in the middle so cross over to the topmost "rib" and wind 4 more turns on there in the same direction , feed the wire down to the righthand pin and solder it onto the pin . The secondary winding stays as is . Carefully reassemble , not forgetting the green plastic spacer on top of the coil former , and solder back into the printed circuit board . T7 is a Mitsumi type ETR0333 .
Next , change C102 (47nF) to 22nF disk ceramic . Remove T8 and dismantle as with T7 and remove the small tubular ceramic cap . I found that a small surgical knife to be ideal here , as you can then just cut the leads of the capacitor , instead of battling to get them off the pins in an orderly

fashion . You will now notice that this time the winding has a tap that goes to the centre pin . In this rig the tap is not used , so we can just rewind as for T7, except this time it will be 1turn second rib from the top and 4turns on the topmost rib back to the righthand pin and solder . Assemble and solder back into the printed circuit board . This time you have to add a capacitor to the print side of the board . T8 has 5 pins , grouped 2 on the one side and 3 on the other : the side with the 3 pins is the primary in this case . Solder a 39pF ceramic capacitor accross the outermost 2 pins of the primary winding on the foil side of the board . T8 is a Mitsumi type 10CA006 .
Now remove T9 and strip down as before . This coil has a pink pot core and is a Mitsumi type 10CB001 . Wind 3turns onto the second rib from the top and 1turn on the topmost rib . Solder back into the printed circuit board and add a 39pF capacitor onto the primary as for T8 .
If your rig was operating for eg. on 28.790 on a specific channel , switch it back to that channel and calculate the new six metre frequency as follows : [10metre frequency] + 21.39 = [six metre frequency] . So in our example it would be : 28.79 + 21.39 = 50.180 . Set your RF generator to that frequency and (using the correct trimming tool) adjust the cores of T7 T8 and T9 for maximum "S"-meter reading . Do not be concerned at this point if the recieve sensitivety is not too good . We still need to change the Low Pass Filter on the transmitter section when we get to that stage .
You will also notice that USB and LSB have swapped around and dont seem to be on frequency ... more on that in part 5

Hello!

I am looking for a very simple and low cost ciruit of a Transmitter and
receiver, such as used in those radiographic controlled toy cars.
Frequency doesn't matter...

Thanks in advance,

Hans Dirne

PS. Please reply by E-mail aswell!

Well, Stephen,
This group is not dealing with homebrew beers or liquor, it deals with
homemade Amateur Radio Equipment. Tasting these might leave a bad
taste in your mouth :)

Don,
I don't have any info on this particular product, but would guess that
it runs proprietary software and may well only know how to talk to
"it's own kind."

Check www.mot.com and try to find your way through the maze.
(it's a BIG site, since Mot is a BIG company with lots of divisions
and lots of operations ... they do have a search engine though ...
that may help you a LOT ...

Good luck and 73,
Carl - wa6vse

CB TO SIX METRES Part2 - The PLL Frequency Synthesizer

By Shawn Baris ZR1EV
PO BOX 212
Brackenfell
7561
Republic of South Africa

Anyone is free to use the following information for private use on the provision that it is not used for commercial purposes . Permission is granted by the author , ZR1EV , to publish and or distribute all or part of the following on the condition that recognition is given to the author . In the case of it being used in a newsletter or magazine , a copy of the aforementioned should be sent to the above adress.

For the purposes of this discussion , I will assume the following :(1)That you have a working knowlege of RF circuitry and techniques .(2)That you have the essential tools to do such a conversion . (3) Basic RF test equipment .(4) The set you plan to convert is fully functional .(5)The set is already fitted with a 40-channel selector switch .(6)That you have the service / workshop manual of your rig .

The chassis I will be discussing is the UNIDEN PTBM048AOX -chassis fitted to a number of CB rigs parading under different brand names . It is a single conversion radio on SSB and double conversion on AM , based on the popular PLL02A PLL chip , and has the Mitsubishi 2SC2166 and 2SC1969 in the TX lineup . Some versions of this rig operated in the "C" band (29MHz Marine) and had a diode matrix , six position channel switch , and could be set to step in 12.5 kHz increments . In addition , these units also had a "piggy-back" pcb fitted near the VCO , containing a 12.800 MHz oscillator . These sets should be changed back to the original 27 Mhz configuration and tested before any modifications are attempted .
The PLL02A(G) chip is quite remarkable in that it contains practically all the components needed for a Pll synthesizer, except the VCO , of course . The chip sports a 9-bit binary divide-by-N-counter , a phase comparator with lock detect o/p (pin6) , and a fixed divider of either "divide-by-1024 or divide-by-2048" , selectable at pin 4 . In this application , a 10.240 Mc oscillator feeds into this fixed divider at pin3 , and when pin4 is left o/c (logic1), will divide this signal by 1024 , resulting in 10kc , which will be your synthesizer "step" . (If pin4 is tied to ground -logic0- the fixed divider will now divide by 2048 , giving you a 5kc "step") DO NOT change the 10.240 frequency . The output of that oscillator is also used in the AM reciever section for the conversion of the 10.695 IF down to 455kc . (10.695 - 10.240 = 0.455) !
At first glance , it seems as if the chip might be able to cover over

5MHz in one go (512 binary combinations at 10kc cannel spacing),but when one has a good look at the spec sheet , the maximum frequency allowed into the divide-by-N counter is limited to 3.5 MHz . So , at 10kc channel spacing , the divide-N binary number of about 350 should not be exceeded to ensure that the chip runs within it's specs . This is the main reason that the mixer xtal (X1) 10.0525 MHz has to be changed .
IC2 functions as both the VCO and as a mixer (C3001/TA7310P) . The interesting thing about this mixer is that it has two inputs (f1 and f2) , and two outputs (f1+f2 and f1-f2) . The difference output is taken off pin9 and the sum output is taken from pin6 . The difference output is fed into the divide-by-N counter input , and the sum output is filtered and is used as the Local Oscillator signal . X1 (10.0525) and Q3 make up the oscillator and doubler stage .
As an example , channel 19 (27.185) , the VCO will run at 17.775 , mixed by the output of the doubler 20.105 by IC2 and will produce two outputs : the sum output, 37.880 and the difference output , 2.330 . The 2.330 goes into the divide-by-N counter , where it is divided according to the value in binary applied to pin7 (MSD) to pin15 (LSD) , in this case a value of divide by 233 . The result of this division is 10kc , where it gets "compared" to the 10kc "reference" frequency from the divide-by-1024 fixed divider chain by the Phase comparator . The output from this "charge pump" is fed to a LPF where the "error" is filtered to DC , so that it can be used to either force the VCO frequency up or down untill there is no error. The loop is now "locked" and pin6 will go to logic1 (5.4V) . The PLL (Phase Locked Loop) .

To be continued...

CB TO SIX METRES Part6 - More on mods

By Shawn Baris ZR1EV
PO BOX 212
Brackenfell
7560
Republic of South Africa

Anyone is free to use the following information for private use on the provision that it is not used for commercial purposes . Permission is granted by the author , ZR1EV , to publish and or distribute all or part of the following on the condition that recognition is given to the author . In the case of it being used in a newsletter or magazine , a copy of the aforementioned should be sent to the above adress.

As probably expected , the story does not end there . If you look at the circuit diagram , it becomes clear that both the frequency synthesizer and the carrier oscillator gets pulled LOW on LSB , not the other way round as implied in Part5 of this series . How could this be ?
The answer lies in the mechanics of mixing . On 27Mc an inversion of the sidebands take place in the process of mixing the 10.695 DSB signal with the output from the frequency synthesizer (coming in from the "high side" of the wanted signal) . The result of the mixing process and the resulting inversion of the sidebands means that one has to generate a LSB signal at the IF frequency to realise an USB signal on 27Mc , Hence the "pulling" low of both signals on both LSB and AM .
When we now convert the set to 50Mc , an additive mixing scheme is employed , and the sidebands come out the "right way round" , with the result that the frequency shifting scheme would have to be reversed . In practice , this is quite a simple matter to accomplish . Some later articles on conversions like these in the Amateur press , circa 1985/6 , would have you believe that it is simply a matter of redoing the labels on the front panel . This will not work and you will have great difficulty in getting the rig lined up to be on frequency on all the modes (if at all) .
Do the following and all will be well . You will see a grey wire running from a point marked (T) next to Q4 in the synthesizer section to another point also marked (T) on the pcb , next to Q18 . Desolder this wire from the PCB where it enters the board next to Q18 . Pull it through toward the mode switch . Next we need to look at the switch itself . There are two sections to this switch . The one section applies full B+ to the final when the rig is either in USB or LSB mode and routes the B+ via a hefty 6 ohm wirewound variable resistor to the final when AM is selected (AM carrier power adjustment) . Leave this as is , and locate the second section of the switch which selects USB/LSB/AM . The wiring from this switch goes to points (30), (19), (21) and (18) on the main PCB respectively .

Point (30) selects AM , point (19) selects USB , point (21) selects LSB originally and point (18) is common . Swap the wires from points (19) and (21) on the switch itself . Take two small silicon diodes (1N4148 or eq.) and tie their cathodes together and solder the free end of the grey wire to this junction . Shrinkwrap or slide an insulating sleeve over the exposed sections of this connection . The two "free" ends of the two diodes (anodes) solder directly onto the tags of the mode switch now connected to point (19) and (30) respectively . For those who are not sure , the end of the diode with the thickest colour band will be the cathode (apologies to those who do know HI).
The modifications to the mode selector is now all done , and you can now proceed to "net" the transciever . Adjust CT1 to net LSB and AM (one adjustment for both modes) and CT2 for USB only . To enable the rig to shift frequency on transmit as well as recieve , using the clarifier as a RIT/TIT controll , remove D5 , and connect the unused end of the clarifier controll to the emitter terminal of Q44 . Be sure to check the settings of CT1 and CT2 after this mod as it will affect the 12'o'clock position on the clarifier . I will discuss mods to the frequency selecting circuitry in part7 ... see you then .

CB TO SIX METRES Part7 - The channel selector logic

By Shawn Baris ZR1EV
PO BOX 212
Brackenfell
7561
Republic of South Africa

Anyone is free to use the following information for private use on the provision that it is not used for commercial purposes . Permission is granted by the author , ZR1EV , to publish and or distribute all or part of the following on the condition that recognition is given to the author . In the case of it being used in a newsletter or magazine , a copy of the aforementioned should be sent to the above adress.

In my introduction to this series , in part1 , I mentioned the channel selector and touched on some of the difficulties encountered when using switches like these . This rig was designed for the American market and as a result are originally fitted with a switch that selects frequency according to the American 11M bandplan . This poses a few problems when any modifications are attempted to change the operating frequency .
For example , you will notice that there are five spots between channels where the frequency increments 20kc as the channel is incremented . Also , the frequency of channel 23 to 25 are not in sequence . Traditionally , mods involving a band change (say , to 10M) would require a piece of paper with a list of channel numbers with corrosponding frequencies typed on it attached to the rig , so one would be able to tell what frequency you are operating on .
In my mods , I inserted an EPROM between the channel selector and the PLL chip to "correct" all of these anomalies. It makes for a tidy, professional "feel" to the mod and makes checking your frequency as simple as looking at the LED readout . As the rig tunes in 10kc increments , one could program the eprom so that Channel 1 (readout 01) will put you on 50.010 , channel 10 on 50.100 , and channel 40 on 50.400 etc. This is how to go about it :
The output from the channel selector switch will be a 6-bit binary "word" that will be unique for each of the 40 channels . We will use each of these unique 6-bit words to adress a specific location in an EPROM where you can program the 8-bit code of your choice . The EPROM will output this 8-bit word to the PLL chip and , voila ! you are on your frequency .
First you need to draw up a truth table . Make a list of all the channel numbers and write down the binary from the channel selector down next to it (you will find it listed in your service manual , or you can read the value by measuring each bit directly off the PLL chip . The pins in question are pin 15 (LSD) down to pin 10 (MSD) , in that sequence) . Next , convert the binary words to HEX . All EPROM programmers I have seen work with HEX .

Select any channel above 27 (ch26-40 are all in sequence) . Read the full 9-bit binary off pins15-7 and write it down . Write down the frequency the rig is operating on next to it . Click one channel up and do the same . The binary should have changed by 1 .
Calculate all the binary codes for the range 50.010 up to 50.400 and when that is done convert them all to HEX . You now have all the information you need to program your EPROM . The eprom has an 8-bit output and the synthesizer chip requires a 9-bit word . In practice you will find that the state of the MSD pin stays the same throughout the 40 channels , with the result that pin7 can be wired permanently to either logic1 or 0 .
I use a single 27C64 eprom , as there are a lot of them floating around surplus . Remember to "pull down" the first six imputs with 1k resistors and tie all the unused inputs to GND . I used a seperate 7805 3-terminal voltage regulator IC to power te eprom and all these components can be mounted on a small pcb or perfboard . I used short sections of ribbon cable to carry the data from the switch and to the PLL chip . It is of course possible to extend the basic 400kc tuning by programming another set of codes for say,50.400 to 50.800 and then use one of the unused inputs to the EPROM to switch "bands" this way . See you in Part8 where we will start the mods to the transmitter .

CB TO SIX METRES Part8 - The Transmitter section

By Shawn Baris ZR1EV
PO BOX 212
Brackenfell
7561
Republic of South Africa

Anyone is free to use the following information for private use on the provision that it is not used for commercial purposes . Permission is granted by the author , ZR1EV , to publish and or distribute all or part of the following on the condition that recognition is given to the author . In the case of it being used in a newsletter or magazine , a copy of the aforementioned should be sent to the above adress.

Whenever any modifications or repairs are done to any piece of equipment , capable of radiating RF energy , it is of paramount importance that the regulations concerning spurious and harmonic energy radiation are strictly adhered to . This neccesitates the use of a spectrum analizer to verify signal purity after these mods are done . I realize that a piece of test equipment in that class is not standard equipment in most "shacks" , but one would be able to most probably approach your local PMR company to check the unit for you to ensure that your output is "clean" before you transmit into your antenna .
The output from the frequency synthesizer is fed via a capacitive divider circuit to pin4 of IC3 , where the IF injection frequency (injected into pin1) is mixed with it to produce the 50Mc wanted output . There are what appears to be two small chokes feeding pin6 and pin8 . L23 is indeed an RF choke , but L3 is not .If you study the circuit carefully , it will become clear that C37 and C38 are in series and connected across L3 to form a parallel L-C Tuned circuit , which at the moment resonates at round 27Mc . C37 and C38 also form a capacitive divider to do the impedance transformation to the imput impedance of the cascode amplifier section of IC3 (input on pin7) . L3 is wound on a carbon resistor of round 400 ohms to lower the Q of this tuned circuit and thus improve stability and to increase the effective bandwidth .
Initially , I used to just take a few turns off the coil , but I have since decided to make a whole new coil instead and just replace the existing L3 with the new one . I used a slightly thicker wire , and wound exactly 15 turns onto a 470 ohm 0.5W carbon resistor . Cover the assembly with heat-shrink tubing , and apply moderate heat till the shrink-tube contracts and holds the windings in place . Remove C37 and C38 , and insert 47pF ceramic capacitor in C37 and a 27pF ceramic capacitor in C38 . I have found that changeing L23 there was no percievable improvement , so , you can leave L23 as is .

The output of the cascode buffer amplifier is fed into T4 and T5 which forms a bandpass filter . Remove T4 and T5 and dismantle as described in Part4 . T4 is a Mutsumi coil, part number 10CA006 and T5 is a Mitsumi , part number 10CB003 . Refer to part4 as to the orientation of the coils.
T4: Wind 1 turn onto the secon rib from the top starting at the leftmost pin . Feed the wire down the gap provided on the former down to the centre pin , form a pigtail , tin , and solder to the middle pin . Feed the wire back up through the gap in the former and wind an additional 4 turns on the topmost rib of the former . Feed the wire back down the gap , tin and solder onto the righthand pin . Remove the internal capacitor , reassemble and solder back into the PCB . Solder a 39pF miniature disk ceramic capacitor across the primary (Ref.Part4)on the foil side of the PCB .
T5:Starting at the leftmost pin , wind 1 turn onto the second rib from the top , crossover at the gap and continue to wind an additional 4 turns onto the topmost rib , feed the wire down through the gap and tin , solder onto the righthand pin . Remove the internal capacitor , replace the black potcore , reassemble and solder back into the PCB . Add a 27 pF miniature disk ceramic capacitor to the primary on the foil side of the PCB . All the secondary windings can stay as is . Remove C42 and replace with a 2.2pF ceramic capacitor . Remove C43 and replace with a 39pF . Remove C185 and replace with a 18pf Ceramic disk capacitor .
We will continue with the modifications to the transmitter in part9

CB TO SIX METRES Part10 - The conclusion

By Shawn Baris ZR1EV
PO BOX 212
Brackenfell
7561
Republic of South Africa

The conversion I have described in Part1-9 has been in dayly use in my shack for many years , and is the only rig I use on the six metre band . I have done countless conversions like this for other enthusiasts and we have all had hours of enjoyment out of them . The rig performs well on most of the modes of propagation found on the six metre band , and with the addition of a couple of extras , produces a stasion that you do not have to apologise for .
I built up a push-pull linear amplifier using 2 x 6146B valves and my rig drives them to max output easily . In addition I constructed a masthead GaSFET preamplifier for that extra edge during weak openings . The antenna will be one of your most important additions (as is the case with any station , on any band) . It would be plain folly to expect "big" results from a "small" antenna .
For CW enthusiasts , the addition of an 800Hz audio phase shift oscillator feeding into the mic input would produce excellent results . I had a TONO 5000E connected to my rig for CW contacts with JA stations and had many QSO's on CW with compliments recieved on the "tone".
The reciever is sensitive enough for serious meteor scatter work , and had worked many stations on this mode . The rig lends itself well to mobile operation and I used to often sit in the early morning traffic chatting to the locals on 50.200 . You would be surprised at the excellent signals on 6M SSB when you are used to FM repeater operation .
Six metres is my favourite band and allways will be , and I hope you will share in the excitement and thrill in homebrewing your own rig and using it on your next DX contact . It was great fun for me and I hope it will be for you too . Finally , an extract from my log book , using this rig,to wet your appetite :

IMHO the best part of QRP is homebrewing. I'd suggest starting out by
building a simple CW transmitter and maybe using your HF
transceiver's receiver. HB receiver can be tackled later. If you
don't want to go the full homebrew route, there are lots of nice kits
out there. Check out Ramsey and Kanga. Good Luck! 73 Bill

CB TO SIX METRES Part5 - Other mods

By Shawn Baris ZR1EV
PO BOX 212
Brackenfell
7561
Republic of South Africa

Anyone is free to use the following information for private use on the provision that it is not used for commercial purposes . Permission is granted by the author , ZR1EV , to publish and or distribute all or part of the following on the condition that recognition is given to the author . In the case of it being used in a newsletter or magazine , a copy of the aforementioned should be sent to the above adress.

It is not my intention to provide lengthy and detailed explinations on the intricacies of SSB or bore those who know this subject well , but to point out some of the basics with particular refference to this particular chassis we are concerned with , and hopefully arm you with the neccissary basic understanding of what we are doing . This will be invaluable when fault finding needs to be undertaken at any stage .
I mentioned before that "USB and LSB have swapped around and dont seem to be on frequency " . To understand what has happened here we have to have a brief look at how SSB gets generated here . The "classic" method of generating SSB involves a carrier generator spot on the IF frequency feeding a balanced modulator of sorts . The resulting DSB signal is fed to switched crystal filters : one for USB , one for LSB , possibly one for CW and one for AM . As you can deduce from this , the manufacturing cost of this approach would result in quite high prices on the finished product being passed on to the consumer . This is probably one of the reasons that most dedicated Amateur Transcievers have the CW filter fitted as an option, rather than a standard fixture , in an attempt to keep the final cost to the consumer low and by implication competitive .
The designers of this (and other rigs) have cleverly sidestepped these problems with some ingeniuety . How AM is generated should be quite obvious so we will not dwell on that now but rather just focus on SSB . Inspect the innards of you rig . You will find only one large crystal filter located roughly in the middle of the PCB . This filter is about 3-2.7 kc wide and is a "LSB" filter centered round 10.6935 . (Some rigs are fitted with a smaller rectangular filter , taking up about half the space . These are "metal-oxide" filters , but for all intents and purposes can be treated the same).
Suppose our carrier generator is set to 10.695 (standard 1st IF frequency) . The 10.695 signal will pass through a balanced modulator chip, IC4 (AN612) , where it is modulated by the audio signal in such a way that

the original 10.695 is balanced out and you are left with a double sideband supressed carrier signal centered around 10.695 . This signal is now fed into the crystal filter where the USB signal is heavily attenuated and the LSB part of the signal is only slightly attenuated (filter insertion loss). We are now left with a LSB SSB signal centred on 10.695 .
What if we want an USB signal ? The answer is to lower the carrier frequency to below the filter passband : 10.692 is about right . The DSB signal will now be generated centered around 10.692 , and after passing through the Xtal filter , will only have the USB components remaining . Note though that the USB signal will be centered around 10.692 and the LSB and AM signals will be centered around 10.695 . Voila ! we generated both USB and LSB with the same filter !
Now you can see that if the frequency from the synthesizer stays constant between "mode" switching , The LSB and AM signals will appear on the band "on freqency" , while the USB will be 3kc "off" . The designers got round this "problem" by shifting the synthesizer output frequency by 3kc when the USB mode is selected , thereby making all of this transparrent to the final user , and all the "channels" RIT exactly at "12'o'clock irrespective of the mode you have selected .
More to follow on this in Part6

CU in Part6

*CB TO SIX METRES * Part9 - The Transmitter section continued

Anyone is free to use the following information for private use on the provision that it is not used for commercial purposes . Permission is granted by the author , ZR1EV , to publish and or distribute all or part of the following on the condition that recognition is given to the author . In the case of it being used in a newsletter or magazine , a copy of the aforementioned should be sent to the above adress.

We are now done with the "encapsulated" small coil formers and the rest of the work can now be done without the aid of a magnifying glass (HI) .
Locate and remove T6 . This tuned interstage coupling transformer is wound on a white plastic former and a lot of care should be excercised not to overheat any of the pins , as the former may deform from the heat and render it useless . The tuned primary of the transformer , can easily be identified . The primary coil is wound from clear enamel coated copper wire and the 1 turn secondary winding is wound using green enamel coated copper wire .
Leaving the secondary winding as is , proceed to remove 2 turns from the "top" of the winding , untill you are left with 5 turns on the former . Form the free end of the wire with a small "longnose" pliers and feed it through the hole in the base of the former where the original lead was fed through . You will now notice thet the secondary and primary windings are spaced too far apart (by the thickness of about two windings). "Pull" the secondary winding lower down on the former (by pulling in the secondary pins with a small pair of pliers) until the two windings touch . Trim the pins to length and using a small hobby knife , scrape the insulation off the pins and tin . Reinsert the transformer , solder back into the PCB and replace C47 with a 27pF Disk ceramic capacitor .
Replace C49 with a 120pF disk ceramic capacitor . Replace L6 with a coil consisting of 13 Turns wound onto a 1.5M ohm 0.5W carbon resistor . Replace C52 with a 47pF 50V disc ceramic capacitor and C53 with a 120pF 50V disk ceramic capacitor . Remove L7 and remove turns until you have 1.5 turns on it . Prepare as with T6 and replace . Replace L9 with a coil made up as for L6 . Modify L11 for 2.5 turns , L13 for 3.5 turns and L201 for 1.5 turns . If you have difficulty locating L201 , you will find it (airwound coil) between point (31) on the main chassis and the inner conductor of the antenna socket . (some rigs have L201 and C201 omitted). Change C51 to 22nF Replace C54 with an 82pF 100V disc ceramic capacitor , C55 with a 330pF 100V capacitor , C184 with a 68pF 50V disc ceramic capacitor and C201 with an 18pF 100V disc ceramic capacitor . As "all coils are not wound equal", You could experiment with slight changes in capacitor values for maximum performance with minimum spurious output . C56 is fitted to some chassis , and can be removed in this mod . L13 is an air-spaced inductor with self supporting windings , and can be streched or compressed for maximum output

When you notice that the peak tuning on T4 and T5 occurs when the slugs are about the middle of the formers , you could INCREASE the capacitor value across the primary by a few pF . The correct point for the cores are about flush with the top of the screening cans . The same applies for the Reciever coils , T8 and T9 with the exception of T7 . T7 should be tuned for the loudest signal , not the loudest "hiss". This is important for a good s/n ratio , so you can dig out those really weak signals on the band . I have found that this occurs when the slug of T7 is a couple of turns from the "bottom" of the coil former . If you cannot get this condition , try changing the value of C100 by a couple of pF .
The rig should now "run up" smoothly . All of the rigs I have done so far, exceeded the original specs on 27Mc on the reciever and practically always got in excess of 10W PEP out of the transmitter (recomended PO) . If you have a "lazy" 2SC1969 (Did a conversion once where I could do what I liked, but could not get more than 8W PEP... Replacing the final did the trick), You could try replacing the final with a 2SC1307 . These devices seem to have more gain at 50Mc . See you in Part10 (final)

I was thinking about modifying a pair of 813's to use
screen voltage instead of grounded grid. If I do this
I know there is more chance of instability, but if I
do this, anybody got any experience as to typical
drive levels I can expexct for full output? With, say
600volts screen voltage, 2500volt plate voltage and
some value of grid bias... ???

Are you still going to drive the filament? If so, any gain change will likely be minor.

Grounded grid PA's are gain limited by negative feedback determined by the ratio of driving impedance to output impedance, since the input and output are in series. Lowering the driving impedance would have much more effect on gain than adding screen voltage.

I hate to cross swords with you Frank, but the only "pip" I have seen on QQV06-40 is the one in the middle of the pins. IIRC, pin 4 in your notation is the BIG pin, the Cathode.

If you are building an amplifier, make sure that you set the valve base BELOW the level of the chassis so that the internal screening ring is on the same plane as the chassis. This improves stability no end. BTW the valves are (allegedly)internally neutralized.

Operating conditions (from memory):

Va 400 - 600
Vg2 200 - 250
Vg1 -70 ish The grid bias was frequently derived from grid current via a 10K resistor - destroys valves with

lack of drive...

Output - 50 watts was quite easy with 600V. not too much more though. Also use large connectors for the anodes, to dissapate heat. They form part of the tuned circuit so take that into account.

There were plenty of circuits in the old VHF manual and RSGB handbook c 1970 but not all were reproduceable though.

If you copy some of the Pye, Cossor or GEC designs, they worked. Beware of the 829/932 double tetrodes, they were NOT neutralised and were a bit hairy, particularly when used in AB1 linears.

5148. 2.4GHz Part 15 devices

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-19 00:00:00 UTC
From: stevem@w6yx.stanford.edu
Message-ID: <5lqj7cepv1@nntp.Stanford.EDU>
Source record: 93927

Recently, while trying to view the output from our local ATV
repeater on 2.4GHz, I noticed a herringbone pattern in
the received signal. Looking closely at the VSB signal
from the ATV repeater on a spectrum analyzer, I noticed
a reasonably strong CW carrier which was the cause of the
interferance.

Going mobile with a small dish and spectrum analyzer, a
friend of mine and I were able track down the source of the
carrier as a car parked on the street about a block
away from my house.

Based on subjective measurements, I suspect that the
device generating the interferance is putting out a
stronger signal level than is allowed under part 15
rules for a non-spread mode. This, in addition to
a violation due to the device causing interferance to
an established licensed service.

I am guessing that it is a wireless vehicle alarm system
of some kind. I'm not sure what the carrier is for.
Possibly the link from the car to a pocket beeper?
Possibly the 2.4GHz RF is used as part of a doppler
motion detector to detect movement within the cab.
In any case, I'm wondering if anyone is familiar with
these systems and knows what kind of options I may have
in dealing with the owner? If its just a matter of
getting him to put the unit of a different channel,
that would be the easiest solution. I'd rather deal
with the problem diplomatically rather than quote rules
and regs telling the owner he has to shut down his
expensive alarm system.

Any reasonable opinions?

Thanks

Steve Muther WF6R

One further note, I have never had trouble using the normal Ferric Cloride etchant on AL, though it works rather fast and you may want to dilute it for more control. Doing it this way removes the worry about attacking the resist with different chemicals.

As I recall, Brian, you were the bandwidth king on rec.radio.amateur.* back then, posting and reposting your megabyte MEGALIST for our "benefit" but the trickle of positive feedback dried up so like many of the news-group big shots you joined QRP-L mailing list. After all they are such a warm and friendly bunch, generous with compliments after any meager accomplishment. Soon a list member asked a question and you could "helpfully" respond with your encyclopedic list of commercial references. Surely they would welcome your major compilation. Not so. Besides being arid in the extreme, the enormous length of your e-mail overflowed many mailboxes, mine included. Others, particularly list members outside north america, paid costly incremental charges for your mammoth files. YOUR PRESENCE ON QRP-L INDUCED MANY TO UNSUBSCRIBE. But to be boring and off topic at length is not sufficient to get booted from the list. The moderator wants a civilized atmosphere with a sense of community, which you damaged with each abusive, hostile response to criticism.

You still have net news for your flames, and the web site is perfect for your information. I see you use the GIF format for paragraphs of text, hey, you're still the bandwidth king!

>--

I think that if you look carefully, you will see that the plates are swaged into place. The brass shaft is cut, the plates set in place, and a tool deforms the brass slightly to hold the plates. Although there are techniques availabe to braze brass, I don't ever remember seeing a cap put together this way. Cutting the slots on a lathe and fastening the plates in place with locktight would probally work. The tough thing would be to make the plates.

: Rick Karlquist N6RK
: rkarlqu@scd.hp.com

Actually, I find that equations DO teach, but the student must
be able to understand. In the case of modulation, all one needs
is a grasp of algebra and trig. Many high school and college
texts will explain in detail the difference between mixing
two sine waves thru a linear and then non-linear element.
The difference being whether the output is just an algebraic
addition of the two signals, or the intended product of the
two when true modulation occurs. Although the mathematical
description gets tangled when laid out, it is really just
use of algebra and trig identities. I never really had an
appreciation of modulation and what was happening by reading
any ARRL handbook until I found standard college texts that
discussed modulation in detail this way. The elegant beauty
of the mathematics is what I love and is what got me interested
in RF.

I'm sorry I dont have any references at hand, but the better
ones will also give simple test set-ups to show the student
how to achieve true modulation using simple rf generators and
signal diodes.

Part 15.245 (field disturbance devices) allows 500mV/m at 3 meters in
this band. This is a pretty hefty signal. It works out to about
100mW EIRP. This is the average value. The peak value can be as high
as much as 20dB hotter.

Well said! So many scientists think because they can MEASURE
something, they UNDERSTAND it. Not so. For example, I have yet to
hear an explanation of why a spinning gyroscope can be balanced off
of one's finger, with it's entire mass off to the side and not fall.
Why does rotation apparently counteract gravity? I sent that question
into Marilyn Vos Savant, the self-proclaimed holder of the world's
highest IQ and never got a reply. Anyone know?

I think that this was one of Bogen's "booster amplifiers" for distributed sound systems. These systems used (and still use) a costant voltage scheme, where each speaker has a transformer with a 70 volt primary and a tappable secondary rated in watts, so you could adjust the output of each speaker for local conditions. A typical distributed system would be the hotel conference room with twenty 8" speakers in the ceiling. If you had this amplifier (we're assuming a pretty old hotel) you might have each speaker tapped at 5 watts (20x5=100). You might also tap the speakers closest to the microphone position at a lower wattage to lower their output and improve gain before feedback. I think the rule was the wattage was supposed to add up to no more than the rated output of the amp, but it could be less than the rated output without problem without problem.

Our local club is building an ATV repeater with an output frequency of 932.25 Mhz, and we are looking for an amplifier with 200 to 300 watts output. For high power we had in mind a pair of of 2C39 type tubes (7289s?) in cavities configured in grounded grid linear service. We can't find a source for such an amplifier except Eimac at a HUGE price.

A company in Jupiter, Florida named High Spec (not sure spelling is right) has been recommended to us, but we can't find any record of this company.

Two questions:

1. Does anyone know how to get hold of High Spec?

2. Can anyone recommend another source for such an amplifier.

Please respond directly to one of the following addresses

Have a look at the Australian QRP Home Page (accessible via URL below).
There's a long discussion about what to look for in a QRP rig (either
homebrew or commercial) and plenty of links to QRP pages around the
world (including commercial suppliers of QRP gear).

Source record: 93940

I'm looking for some bandswitch wafers to put in an SB-220
which has been converted to 160 meters.

Specifically I need
1) a 6 position ceramic progressive shorting wafer
to progressively short the plate tank coil,
2) Another wafer to add extra loading capacitance for 80 and 160 meters,
only 2 of the 6 positions need to be present on THIS wafer.
3) still another wafer to add extra tuning capacitance on 160 meters,
only 1 of the 6 positions needs to be present here.

I would appreciate hearing from anyone who can help.

5170. Simplex Repeater Help

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-20 00:00:00 UTC
From: Jason's News <jasong@bim.com>
Message-ID: <864138924.233537@virtual.icr.com.au>
Source record: 93941

Has anyone tried building the simplex repeater as shown in '73 magazine? I'm looking for ways to enhance the one that I built.(extended record, phone patch,ctcss, dtmf decoder, etc). The base configuration works very well, but I feel that this circuit has a lot of potential in the way of expansion.

Any info would be appreciated.

Please email to jasong@bim.com

Thanks!

Amateur Radio Operators
From the State of Michigan

We the Amateur Radio operators from the State of Michigan do hereby agree to continue to abide by all the rules of Amateur Radio. We pledge to improve the amateur radio bands, and teach new hams joining the hobby the correct operating procedures which should be followed on the amateur bands. By doing this, we are petitioning the American Radio Relay League in our fight to help clean up the language on the Amateur bands, and are looking for civility/politeness in conversations. By showing our support in this petition, we are hoping that the American Radio Relay League can help us fight the language that we are hearing on these bands.

We are asking the American Radio Relay League to help in this clean up by: Hosting several national forums on this problem, and how it can be addressed, We are looking for a promise from the ARRL to report on how enforcement is currently done. We are also looking for a promise from the ARRL to create a sort of self enforcement mechanism, and possibly create a large fine mechanism that will generate enough money to help correct this problem. We realize there is such a thing as freedom of speech but, there are also the words such as civility, and politeness.

I Deborah K. Kirkbride KA8YKK am asking all amateurs in the State of Michigan to please sign this petition, and send it to me at the following address: 1315 Center Avenue, Apartment #1 Bay City, MI 48708. I will in turn when enough signatures are gathered be sending all petitions received to the ARRL.

Please make copies of this petition and pass it along to other clubs, and Amateurs in you area. Please help me in this fight to get the Amateur Bands back on the right track and keep them there.

If you are not from the State of Michigan please feel free to download this off my web page http://www.concentric.net/~ka8ykk change the state name to fit your own and get this started in your own state. You can forward them to me and I would be more than happy to submit them to the ARRL with the State of Michigan.

Thanks
Debbie Kirkbride KA8YKK

The old Sears Roadtalker converts nicely to six. Appended are some thoughts...

Dick - w7wkr

Greetings

Well, what you do is obtain a schematic for the radio you choose to buy and then look at the sections that are specifically tuned to the original "use" band (e.g. those circuits that are tuned to 27.xMHz).

All you have to do is change the L's and C's in those circuits to resonate at 50.1MHz. To do this you can scale the reactances so they are the same at 50.1MHz as they are at 27MHz. All of the I.F. circuitry remains UNCHANGED.

For example, if the Xc for a capacitor (1/(2*PI*F*C)) is -J100 ohms at 27 MHz then you need to make -J100 = (1/(2*PI*51.1E6*C) and solve for "C" (change the -J100 to 100 and solve for "C"). Do the same for the inductors Xl = 2*PI*F*L - determine what the reactance is at 27MHz and use an "L" that provides the same reactance at 50.1MHz.

Once you have changed the appropriate input/output RF stages, then all you have to do is determine the NEW crystal frequency required to get 50.1MHz +or- LO = I.F. In many cases, the L.O. freq involves a freq synthesizer output that is mixed to another frequency and THAT freq is the actual L.O. freq.

I was fortunate in that the Sears Roadtalker 40 allowed me to use the original crystal and all that was required was to use the PLL freq + the crystal freq instead of the PLL freq - the crystal freq to generate the final L.O. needed to get on 50.1MHz.

Good luck,

> drive levels I can expexct for full output? With, say
> 600volts screen voltage, 2500volt plate voltage and
> some value of grid bias... ???
> Doug, N4IJ

I have three tubes in parallel, cathode driven with a silicon diode voltage doubler from the cathodes to feed the screens with about 240 volts under full drive. This is similar to the classic G2DAF circuit, but sticking to cathode drive gives better linearity. Control grid bias is obtained with a 1 kohm resistor to ground.
Ua: 2,3 kV, Ia: 0,66 A Ig: 0,1 A. Output is 750-1000 W depending on band with 100 W drive. IMD is -34 db or better below PEP. The bias resistor increases efficiency 7 percent.
When time permits I will change the doubler to a tripler, but I doubt that it will make much difference.
If your problem is a lack of driving power this information won't help you, however. Look in e. g. 1967 Handbook.

George Carlson (geotek@comwerx.net) wrote:
(In response to a question about brazing aluminum capacitor plates to
a brass shaft:)

: Although
: there are techniques availabe to braze brass, I don't ever remember
: seeing a cap put together this way. Cutting the slots on a lathe and
: fastening the plates in place with locktight would probally work. The
: tough thing would be to make the plates.

I recall seeing some old caps with _brass_ plates, not aluminum, which
were soldered or brazed to the shaft. Been a _very_ long time ago, and
they were old then.

If the original poster has access to a lathe, the easiest answer may be to
simply turn the whole rotor out of a solid block of brass (or possibly
aluminum). Another way I've seen it done is to stack plates on a shaft
with alternating spacers and plates. Then threads on an end of the shaft
allow a nut to clamp it all together.

As for making the plates, it might be best to contract with a sheet metal
shop to do it for you...some with NC equipment can set up for small runs
pretty economically. But it's still likely to be in the hundreds of
dollars for a minimum run.

>this one out, however, here in the US, it is getting increasingly
>hard to find older ssb rigs based on the pll02a chassis.

Well, I don't know if I can help you too much, since I haven't tried it myself yet... The article is written by a ham from South Africa, and I just picked it up on the packet-radio network, and so I really don't know too much about the background of the article.

In part 2 of the article it is mentioned that the modifications was performed on a UNIDEN PTBM048AOX chassis (in a book I have, it says that PTBM048AOX is actually a CYBERNET chassis), and as far as I can find out, that includes the following radio makes:

AWA/Thorn 1503
Boman CB950
Colt 480, 485DX, 1000, 1200 (Excalibur)
Gemtronics GTX77
G.E. 3-5825A
JC Penney 981-6247
JIL MPL-5, SSB-M6
Lafayette Telsat SSB140
Midland 78-976, 79-892
Palomar 2900
RCA 14T302
HyGain 2705 (V), 2785, 3108 (VIII)
Truetone CYJ4837A-87

The above list of radio makes is taken from the "Cybernet Export Service Manual", by Lou Franklin, and so it seems like they belong to the Cybernet family, rather than Uniden.

That same manual also refers to something called "SAMS Fotofacts" for pictures/layout of these radios, but I am not sure where of what that is.

It should also be noted that there is a whole range of CB radios that are using the PLL02A chip, and the list is far to long to include here.

Hope this info may be of some help...

I will also be posting some last comments from the author of the article, under the heading "CB2SIX extra info" , which may be of some help.

73 de Anders / LC3HAT, Email: anderskv@online.no

5177. CB2SIX extra info

Source record: 93948

The following is written by ZR1EV, Shawn:

Hi all
I have recieved quite a lot of mail re the CB to six metre conversions described in the 10 parts of an article recently . Instead of replying to each one individually , I will reply in a bullitin , as everyone basically wanted to know the same thing .
The reason I mentioned a particular chassis part number and not the rig(s) by name , was that the bullitin went out to SIX@WW , and the same rig will go under different names in as many countries . The Uniden chassis under discussion is fitted to a number of local rigs . These include :
Major MSB6205
General Electric 3-5825A (A-model)
Tedelex 6000 ("old" model , pre-1985)
Tedelex 7000
etc
There were also a couple of rigs (the so-called "B"-models) that use the same synthesizer configuration and similar circuitry , but have the IF/audio and the synthesizer/switching/RF sections on two separate boards . These are also good candidates for conversion . The difference is that the bandpass filter is switched between the RX and TX , opposed to each circuit having its own tuned circuits as found in the Major chassis . (T204/T205 in the "B" models , and T8/T9 - T4/T5 in the "A" models . So if you want to try ane of the "B" model rigs , you will end up winding 2 coils instead of 4 ! The part numbers are even the same , so you can wind them the same way. T204 is part number 10CA006 and T205 is part number 10CB003 .
The "B" models include:
All of the Midland base stations("old type",PLL02A(G) based synthesizer)
Midland 79-891
Genaral Electric 3-5825(B)
General Electric "Super Base"
etc
I have also done a few so-called "export" rigs ...120 channel all mode (FM/
AM/USB/LSB) . The sections needing modifications were for all intents and purposes the same , but the synthesizer used a bank of 20 Mc Xtals (3 in all) in place of the 10.0525 & doubler configuration used in the Uniden Chassis .
The rigs I had done were the Lafayette 1200FM (also goes under a number of different brand names)

Source record: 93950

Hello Fellow Hams,

I have built a 8877 2M amplifier. Now I need a relative output power indicator for tune up purposes. I have been thinking of a microstrip design. The problem is what dimensions are recommended to be used with a 1500 watt amplifier? Will G10 epoxy board with 1 oz copper good enough? 108 mill trace will produce a 50 ohm impedance. What spacing do I need for the detector loop? What length do I need for the 50 ohm microstrip and detector? I expect to see somewhere like 275 volts or more at 5.5 amps or better going through the microstrip. I was considering the spacing to be around 200 mils but I don't know if the detector voltage will be too high. I would like it to stay under 25 volts if possible.

>73 de Len SM5DFF

Hi Len,

Don't ever do an three tone IMD test on that circuit. The G2DAF
circuit is a very poor IMD performer if the input level is
time-varying in amplitude, like voice modulation.

Screen voltage needs to be held constant, and the eciter needs to see
a constant load. Systems like the G2DAF load the exciter most at
peaks, and not at all at low levels.

The only thing that saves the G2DAF circuit is the heavy negative
feedback from the use of cathode drive. It tends to counteract the
distortion and swamp out the varying load offered by trying to
extract dc bias voltages from the exciters output.

The G2DAF system has NEVER been popular with amateurs, and never used
in a commercial PA. There are no benefits to offset the increase in
distortion.

Hello homebrewers!

I have designed a small DSB rig for 80 meters. Three rigs have been built so far and all are working UFB. If you are interested, have a look at my homepage at:

http://home4.swipnet.se/~w-41522/

Look for SM6LKM's DIY QRP Corner. The name of the rig is Optimist-80. Schematics, PCB layout and building instructions are available for download. Free of charge, of course.

You won't believe how much fun a single watt P.E.P. is able to produce until you have tried it yourself!

Source record: 93864

For fun, I recently bought an old IBM PCjr at a yard sale. I thought I might use it for packet, or maybe to fool around with some assembly language programming (trying to learn some things about microprocessors).

I want to see if any of you have the following parts for an IBM PCjr for sale:

IBM PCjr original keyboard with cable and working infrared
IBM PCjr connector for TV
IBM's adapter cable for the IBM PCjr Color Display
IBM PCjr serial adapter cable
IBM PCjr joystick
IBM PCjr adapter cable for cassette
any cartridges
lightpen?
books for the IBM PCjr, especially any discussing assembly language programming

I'm not a collector, just wanting to find some of these things to play with.

Anyone know of a minimal telecommunications program I can use with packet that comes with the assembly language or Basic code?

Thanks,

Keith, N3KXZ

>73 de Anders / LC3HAT, Email: anderskv@online.no

I have performed the mod twice...It really does work (why shouldn't it
!)
The first was a Colt 485 Black Shadow, the second a Citizen MPL-5.
I would say that the mod is not for the faint-hearted
tinkerer...better left for a seasoned experimenter.

Cheers, Hugh VA3TO

5187. Need info for Palomar 225 mobile amp w/auto side band

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-21 00:00:00 UTC

They are not common, but I have a variable capacitor with nicely brazed plates. With brass it should not be too hard, though I would seriously consider using 95% tin 5% silver alloy. It is strong and you won't have much annealing or distortion (the latter you can beat by doing the job in a furnace, to a large extent.)
Because I wanted to make a special, very low inductance capacitor I have though a little about making plates and the easiest way was either to make a bunch of disks by first making the holes and then roughing out the disks, followed by turning the whole batch in a stack on a lathe. Finally, cut them in half, carefully!
It would be only slighty harder to make a punch and die to cut the disks practically to finished size. Probably making full disks is less work unless we are talking about several capacitors. Such a punch and die set is then just lathe work, with the force to work it made with the bench vise.
Quite frankly, I would probably select copper instead of brass. It is a predjudice but there would seem to be no trouble with zinc in a slow brazing process.
I did not receive the original posting so I don't know the purpose of this capacitor but in a high current application like transmitting or rf-induction heating the brazed capacitor is probably worth the effort.

If I'm not mistaken, microwave ovens work on or near this band. You
may be picking up leaking radiation. If they are using this band for
industrial heating, you may actually be doing them a big favor by
informing them that their shielding leaking. I would tread cautiously,
though. The source may be the primary user of the band and Ham Radio
is secondary.

5208. help pse: CTCSS tone on FT690r Mk1

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-21 00:00:00 UTC
From: Chris Philpot <Chris.Philpot@btinternet.com>
Message-ID: <01bc6634$6d1422e0$LocalHost@fred>
Source record: 93887

Hi fellow 690 owner,

This is a repeat of a previous posting, there were no replies to the first request for help!!!!

Thanks for taking the time to read this message, and if you are able to help me, please take the time to do so, I will acknowledge all replies.

Close to where I live, a new 6Mtr. repeater has just started up....GB3RR

I have the desire to work the repeater, but have an aging FT690r, and the repeater requires a CTCSS tone at 71.9 Hz.

Okay, so I have a CTCSS board, and fitted it to the rig. It works!!, but where does the tone need to be injected to the TX chain?? If you have worked on this job, I would be very pleased if you would share the information with me.

Also just one niggling doubt in my mind....my freq. counter can only go to 1Hz resolution, and I have set up the tone to just "flicker" between 71 & 72 Hz, how accurately does the tone need to be set?

I shall look forward to receiving, your replies to my plea for help, and also to getting the rig working on the repeater.

If you are outside the UK and want info. re British 6Mtr. repeaters, feel free to E-mail me for details.

73 for now,

de Chris G6KBC

FWIW...The principle is the same as the 50 mhz to 14 mhz (6 Meter
Transverter) receive section schematic at my www page. Filters need to
be at the frequency of interest (or span of frequencies) rather than
where they are. Also, depending on the receiver used, you may want a
vfo for more tuning range (in place of the crystal local osc).
Food for thought anyway...

Woody,

Somewhere in this stack I've got an article that I clipped from Popular Electronics in the late 80's or early 90's. If you can't find it from that (addmittedly scant info), e-mail me and I'll dig it up and scan it for you.

I found the floppies, it's http://www.hamradio.si, it's a bit funny,
the netscape screen goes blank and eventually the transfer rate starts
to decrease, at that point hit STOP and it displays the info, click on
the Hardware line and it takes you on etc. When downloading the files,
use SHIFT Right mouse button and it downloads it at a more normal rate.

How about using a transistor AF amp. output transformer to convert the
impedance of a low-impedance pair of headphones.

Avantek were bought by Hewlett Packard.
Some of their products were absorbed into the HP line,
but many were discontinued. Transistors
may be found in the HP microwave components catalogue,
particularly GaAs FETs which seem to have kept their
Avantek prefix (e.g. AT...).
HP has numerous distributors.
Have a look at http://www.hp.com/HP-COMP/

>
> Regards - Bry

The ouput impedance will nominally be 144 ohms @ 100 watts and 120 volts output. It was probably meant to drive a 150 ohm line, with line to voice-coil transformers at each PA location.
To use as a modulator you would need to match the plate impedance of the amplifier you are modulating. As an example, if the transmitter ran 126 watts input and drew 180 Ma. at 700 VDC, the nominal plate impedance would be 3900 ohms. You would thus need a 150 ohm / 4K ohm transformer capable of handling at least 65 watts for 100% modulation.

I'll agree lawbreakers should be thrown in jail or at least regularly
repeatably predictably have their gear confiscated early and often
enough that there would be some disincentives.

However.

One does not need MARS/CAP authorizations to use the AT-600's
keyboard mod. There are several good and lawful reasons for owning a
transceiver with wide-open TX/RX.

One is as a cheap signal generator for test equipment that is always
in Coax, never in an antenna. (This is how Cable companies get away
with using "our" frequencies, remember?)

The more relevant one to Hams is building transverters to bands one is
licensed on. Wide open from 100-200 and 400-500 gives rather more
flexibility in picking up-converter LO frequencies than that which
is required of matching the narrow range of a type-accepted transceiver.

[NOTE: Follow-up-to: set to r.r.a.equipment; if commenting on this
paragraph or below, please redirect to r.r.a.homebrew which I've
cross-posted. -- n1vux]

Both of these require a low-power setting or an attenuator. If the
manufacturer wants to justify legal use of this keyboard mode, a keyboard
setting for 50uW output (exciter only) would be a good one.

If I was optimistic about having time to get into uWave bands anytime soon,
I'd be rushing out to buy one of these (and would have grabbed that HP
signal generator for 7-11GHz at the last MIT :-)...

I'm wondering if a really wide open transceiver like this would make a
multi-band transverter possible, using band-switched resonators like
are used on multi-band HF rigs? I'm guess the reason this wasn't done
in the past was the switch leads would have too much stray reactance,
but with microwave switching diodes perhaps all the band modules could
be laid out together? Probably wouldn't fit ... [see r.r.a.h note above!]

I have a pair of used 211 triode tubes for sale. Both are RCA and one is dated 1942. The filaments are good and there is no visible carbonization inside the glass envelopes or wear on the plates. They look as though they have been used very little but I have no means to really test them. Both tubes come with unused Johnson 211 ceramic tube sockets. $75 each which includes shipping within the 48 states.

<EAFqt7.AtH@freenet.buffalo.edu>...
> Need instruction on how to braze/solder plates in a variable capacitor.
Need to join aluminum plates with brass support rod.

Not impossible if you:

Make the parts a good mechanical fit before soldering.
File, form, tweak the parts until they are just exactly right. No gaps,
please!

Set up a jig to hold the parts to be soldered.
So when you solder, they will be correct when done! Holding the parts by
hand
is NOT good enough.

Clean parts.
No oxide on surfaces. Use very fine #00 steel wool as last step, but
don't
leave any strands!

Degrease parts.
Use a solvent like isopropanol (rubbing alcohol) or pure acetone.

Use the aluminum solder paste that guy always hawks at hamfests.
It's one of the few real appropriate uses I can think of for the stuff.
You will need
a small torch, and MOVE IT AROUND the workpiece a lot so you don'e melt
the
aluminum plates. Practice first on some scrap pieces so you can see what
it
takes - aluminum heats slowly because you are heating the whole piece due
to
the very good thermal conductivity while with brass the heating is more
localized
to where the flame is. Thicker parts will require that you have the flame
spend more
time with than the thin parts (thermal mass again). BE CAREFUL TO NOT
OVER
HEAT ANY PARTS. The object is to raise the entire piece to soldering
temperature
at about the same time, then if the thing is clean, the whole thing should
just about
solder itself together all at once, almost magically.

Soldering a complex piece is an art and a science and is difficult, but not impossible, to do
without some practice. Once you can do it, it's wonderful, though!

>
> Thanks & 73, Paul Kluwe, W8ZO

Hi, Paul!
There is no longer such thing as an effective plate choke that covers all 9 bands. What most quality amplifier makers (Creative, Alpha, Henry, et al) are doing is using two chokes; shorting one out for 80-10m. The B&W 800 and 802 have their resonances "parked" between bands, and have enough inductance to be effective on the 8 higher bands, but the amount of 160 meter RF current that gets by the choke is very great. This allows the RF to wreak havoc on the bypass capacitors and electrolytic caps in the power supply filter. (if used) In some cases, the RF makes it all the way out the back of the amp, and radiates through the a.c. power lines all over the building!

Just mount a second choke of 130-200uh at a right angle to the 60-90uh choke and switch it in/out with a spst vacuum relay across its terminals. The Alpha 77DX/SX amps have an unused position on the input band switch (160 meter position) that can be used to ground one end of the coil on the vacuum relay. Other amps can be adapted with micro switches etc. that make when the band switch is positioned to 160m. I always add a .01 ceramic disk H.V. bypass cap to all the ones that are already there to complete the mod.

A very good choke can be easily wound with H.V. magnet wire around a G-10 fiberglass tube of convenient diameter. #24 wire is good for several amps. Most modern magnet wire used by motor rewinding shops is coated with a silicon varnish that is good for 6000v + without having to space-wind the turns.

There are lots of compromises that can be used, but the circuit I described is the only effective way I know of to cover all 9 bands without a choke fire or RF where you don't want it!

(((73)))
Phil, K5PC

Should be fairly simple. A single NE602 chip (which contains an oscillator and a mixer) would be a reasonable starting point. I would favour crystal control for best stability.

Another option is to use a NPN transistor xtal osc and a dual gate mosfet mixer in a normal converter circuit. The ARRL Handbook may have a suitable circuit that could be modified.

I built a SW receiver using a car radio. If you are willing to put up with backwards tuning on the lower ranges, you can cover 3.5-7.5 MHz with a 5 MHz and a 6 MHz xtal (both fairly cheap). Make sure your front end preselection is OK though - use two or more tuned circuits before the mixer for best image rejection. With care you should be able to eliminate coil switching if your front end can tune 3.5-7.5 MHZ in one sweep and you are using an untuned output to the car radio.

You may also want to check out SM0VPO's Home Page - I think this has a circuit for a converter. You can get to this page through the Australian QRP Home Page (URL below).

An additional question:
how can I test a vacuum variable offered at at flea market ?
I have heard that there is a way to estimate the vacuum quality.

Although I, personally, would find your idea quite amusing, I (nor anyone
else in this newsgroup) could condone it. If you really want to do this then
I would suggest getting a good book on the practical aspects of radio (such
as the ARRL Handbook) and reading it. I have to say that I'm quite surprised
that you can hear the McDonalds transmissions on your radio, as I would think
that they weren't allowed to xmit in Band II FM but it might be a 2nd
harmonic of their xmitter (in which case you xmitting on 92MHz would not
affect them, (unless you overloaded their rcvr's frontend)).

Hello, I'm looking for Mod xfmr or output xfmr for 2 X 807 at 100 watts.

I think this would require 12000 ohms on the primary side.

For a speaker tranny I need one to go to voicecoil, i.e. 8 ohms.

For a mod tranny I need one that would feed something like a pair of 807s or a pair of 6146s in the RF final.

Also need larger mod trannies of lower primary Z. 5K - 8K or so. Even better if you know what B+ and tube compliments they were designed for.

What do you have?

Yes, they are still going strong. They publish a catalogue every six
months that is available from newsagents like Smiths. I think their new
one has just come out, although I haven't got it yet. They still sell RF
stuff, including MCL DBMs, and lots of kits.

They have an email address: mailorder@cirkit.co.uk

The UM9401 is a pretty good PIN diode for HF .. but the
parasitic capacitance may be higher than you'd like for
2m/70cm ... I don't have the data sheet in front of me, but
I know it's a good HF device for up to at least 100W, with
a minority carrier lifetime of (I believe) about 2 usec.

I would also suggest that you look thoughtfully at the
circuit diagram and the line lengths ... I believe you need
to rethink things just a bit there in terms of a 1/4 wave section
inverting the impedance at the other end and 1/2 wave section
repeating that impedance ... 33cm doesn't seem quite right,
nor does 1/3 of that, as the diagram seems to indicate.
Or am I interpreting your instructions incorrectly?

>Thanks

This sounds like a fun project. I'll guess that you are building
AES's model K-405 one tube regen receiver. It's the only one
in their 1996 catalog. Maybe they have more models now.

What do you hear?
If you are not tuned to a station you should hear a continuous
hissing noise that will change as you adjust the regeneration control.
At some point in the adjustment the circuit goes into oscillation
and the sound will change abruptly. There is no squelch on a
receiver this simple, so you should hear something all the time.

What are you using for audio output? If you are using headphones
this circuit requires high impedence headphones. Typical
hi-fi stereo headphones are quite low impedence and will effectively
short out the audio.

Since you have a multimeter try checking some voltages and currents.
Check the voltage across the filament and from a common/ground point
to the plate. Also try checking current drawn from your "A" (filament)
supply (1.5volt battery) and from the "B" (plate) supply (45 v battery).
The filament will draw a few tens of milliamps (maybe as much
as 100 ma) and the plate a few milliamps (maybe less than 1ma).

What tube are you using? The catalog lists several options
for the K-406.

How much of an antenna do you have? You will probably need
several tens of feet of wire.

What frequency range is it set up to tune over? The catalog
listing doesn't say.

Hope this helps a little. There are some real experts on
regenerative receivers somewhere around the net. Maybe one
of them will have some comments.

73,
Gary

>of the mathematics is what I love and is what got me interested
>in RF.

I think the handbook accomplished its mission for you: it got you
interested enough to go learn the rest of the story.

According to Dave N., the handbook is supposed to be written
at a 10th grade level. That probably rules out trig.
Dave watered down a lot of what I wrote because of this
constraint. So basically, the answer is that the handbook,
as the ARRL defines it, is that wrong venue for what you
want. Is it the ARRL's mission to duplicate college textbooks?
I don't think so. In fact, after realizing this, I gave up
writing for the ARRL and instead now write for the IEEE, so I
can do my own thing.

Perhaps there should be a mission statement at the beginning
of the handbook to properly calibrate the reader's expectations.
The fact that the handbook is not of engineering caliber doesn't
mean it doesn't have a lot of useful ideas in it. Maybe it
should be called "Yet another handbook, FWIW" instead of "THE
Handbook":-)

>I'm sorry I dont have any references at hand, but the better
>ones will also give simple test set-ups to show the student
>how to achieve true modulation using simple rf generators and
>signal diodes.

As Heathkit proved, the mere fact that you can build a working
circuit doesn't prove that you understand *why* it works.
OTOH, there are professors who know why things work, but
don't know how to solder.

While looking through the U.S. question pools a few years ago, it appeared to me that all questions are not answerable at a 10th grade level. So I find it a little strange _if_ the question pools contain technical questions that the answers can not be understood by reading the handbook.

Does the question pool committee check if all the technical questions can be found in the handbook ?

Purchase from Radio Shack the mini-engineers book of communication projects. This book runs about $2.00 and includes several fun radios to build. These little radios can be built from things most of us have hanging around in less than half an hour. They are all AM and don't have the sensitivity of $1000.00 radios, but I think you will be surprised at the performance. Let me know how things turn out.

Hello,
I am using (and also do maintanance on some nodes, have built many of hardware..) and it works. The result is, that 1/2 users of packet radio users in s5 are using at least 38k4 user access with simple WBFM radios. Most of them are built by the users themselves, and that's what HAMRADIO should be, isn't it?
At the moment, there is at least 6 links in S5 on 1.2 Mbit (PSK radios for 23 and 13cm) and we also already have users on 1.2MBit 23cm.
The main problem is - if you are used to 'normal' PR, that the network in other parts of Europe is still at rates 9k6, somewhwre there are few 19k2, but much more under those antique rates. I tried some times to go through the network to reach for example northern part of the Germany, but you get old before you reach it...
What's the reason? Did HAMs become lasy? Or the only way to get a RIG is to go to the shop and simply buy it, and if the far-east toys are not capable of handling more than 9k6, than stay there....

5271. Light-Control Interference

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-23 00:00:00 UTC
From: tsimonds@icanect.net
Message-ID: <5m4i2kiis1@news.icanect.net>
Source record: 93848
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.antenna

This may not be the proper group, but here goes anyway. No flames, please! Just guidance....

This concerns interference TO a light control, not the more common interference BY a light control.

The device is Radio Shack Cat. No. 81-2771 Touch Control. It gives you dim, mid, bright, and off control of a lamp by successive touches of any metallic part of the lamp or its cord.

It works just fine as long as I am not on 40 or 80! On those bands (SSB or CW), the lamp cycles though various stages of on and off in step with wither my voice or CW. Most annoying to the XYL who is trying to watch the tube in the same room with the lamp!! No problems on 20 up.

I'm running a clean TS440 barefoot through a tuner and LPF on 40 and 80 to a dipole with a feed point at about 50 ft. on a tower about 25 feet from where the affected device is located. The other three bands (20, 15, and 10) are through a tribander at 52 ft on the same tower.

It's probably just a case of fundamental overload in the circuits of the device, but has anyone had this trouble and found a fix?

A neighbor called early on and said she had seen our lights flashing on and off. Was there anything wrong? Most embarrassing. I could just reach over and turn off the lamp at its switch, but that's not the way a ham solves a problem like this!!

Thanks for any help--

No, this is not true. HAMRADIO is also about using the latest technology. Using WBFM on 70cm is not what I consider the best possible solution. The transceivers you are refering to need at least 200kHz of valuable bandwith.
Here in Germany we try to setup some 200kHz wide user access points (76k8 FSK). The transceivers are already developed but what is missing is the permission to use them. Currently there are some ATV guys who think that AM-ATV is still state of the art :-(So it may be a problem to get 2 200kHz wide channels (for duplex) on our 70cm band here (remember: we only have 430-440MHz).

> At the moment, there is at least 6 links in S5 on 1.2 Mbit (PSK radios

Same problem on 23cm. We have 2 segments for packet radio - each 2 MHz wide at the corner of the 23cm band. 2 MHz is not enough for a single 1.2MBit BPSK signal! And what we want (and what we actually achieved here in Germany) is a *network*, so we really need more than 1 channel :-(Given the 50kHz wide channels 19k2 is not too bad. Using 4FSK 38k4 should be possible. Of course we want and we need higher data rates for our interlinks and our access points. But with our frequency allocation

scheme here this is possible only on 6cm or 3cm. 13cm may be used in some areas (we have a special license for 13cm), but may be a problem where 13cm is used by the primary user of this band (amateur radio service may not cause interference).

To put it into a nutshell: give us bandwidth and we provide you with a network like the on you have in S5. It is not a technical problem it is more or less a "political" one. The HAMs here are not lazy and 99% of the equipment used in the digipeaters is homemade (mainly RMNC hardware and "Interlink" TRX I und III for FSK on 23cm).

From: chrisl@netdoor.com
Message-ID: <5m4ilh$667$1@axe.netdoor.com>
Source record: 93851

Thanks for all of the help on the reciever. I learned something basic from this. Just because the battery is bought new doesn't mean it's not dead. I'm picking up AM and will be fiddling with different coils to get SW freq. I got a number of responses and learned al much from them as I did from the instructions.
Chris

Thanks for the info. I learned something basic. Just because you get a battery new from the electronics store doesn't mean it's not dead. (grin). I was suprised that I didn't get a howl from the set with the regen pot on full though.

5276. TV 75/300 ohm balun for 3W transmitting?

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-23 00:00:00 UTC
From: cromwell@sclera.ecn.purdue.edu
Message-ID: <5m51at$k0e@mozo.cc.purdue.edu>
Source record: 93853
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.antenna

I'm planning to build the dual rhombic antenna for 1296 MHz, described in a recent "QST", and am considering how to transform its 300 ohm to (roughly) 50 ohms.

What's the current thought on using television VHF/UHF baluns for low-power use at amateur UHF frequencies? My transverter will have 3W PEP, which I *think* may be adequately handled by the little handy easy-to-replace TV units.

Bob Cromwell KC9RG

The best solution I know of,at least the one 2 or 3 of my friends
used,is to disconnect the device,open the door and throw the thing as
far away as possible.Your troubles will suddenly be over:<)
One friend of mine wrestled with this problem for a month or so before
he used the above solution.
If you come up with an alternative solution let us know.
Good luck!!!

From: acatalan@pipeline.com
Message-ID: <5m5el0$c0c@camel4.mindspring.com>
Source record: 93758

Hi, I need the 2010 schematic to find the best pll vfo tap-off point
to feed a buffer that will mix with a crystal to provide a transmit
frequency equal to the receive frquency displayed.
I dont know how bad the phase noise is but the CW notes
received sound steady enough to me.
This will be homebrewed to TX CW on either 40, 20 or both.
the mixing crystal can be set up to provide an RIT function as well
if done with care when ordering the crystal frequency.
Tell me if I am crazy. Tell me if I am not.
I guess I just need the schematic not the whole manual.
I do have use of a 100mhz 2246 Textronix scope to work from there.
Thanks, Tony - WW2W (not a vanity call: I ain't that vain.)

See my page at:

The V/U baluns become quite lossy at YHF TV freqs- Winegards is one of the best however. The real problem will be its balancing properties- I suspect they will leave a lot to be desired. At TV freqs you can put a balun on the input of a FSM with the twin lead legs spread. Then short them together and notice how far down the common mode currents are reduced- it gets worse and worse as freq increases.
You are probably better off building a 4:1 coaxial balun out of a short length of 141 semi rigid coax and living with the theoretical 1.5:1 V.S.W.R. (75/50). At least all will be balanced.

>73, Bill W7TI

I will take an educated guess:
As we know acceleration up or down requires a force.
It is easy to picture speeding up or braking a spinning bicycle wheel
with one's hand as up/down accelelation.
Not so easily pictured is the changing of the axis of a wheel as also
a type of acceleration since you ARE changing the direction (vectors)
of the particles of the wheel. The spinning wheel resists. It feels
strange because we usually don't encounter this force between our
hands everyday when holding such a wheel in a demonstration.
When a top spins on it's side without falling it is because the
earth's gravity (an acceleration force) cannot overcome the
momentum (mass with a speed in a particular direction) needed to pull
it off it's axis. A particle in a wheel has an average speed but at
any point in time it has a velocity (speed in a particular direction).

When the spinning slows down (by friction) or if the gravity were to
be increased (as on Jupiter) the top will teeter and fall when it's
momentum force falls below the combination of the above forces.
In space, with little friction and with microgravity, spinning objects
can take a hell of a long time to teeter but they all do eventually.

I discovered that most who build this rig don't use the component-side ground plane as specified. Actually, my problem was not with the transmitter at all. I build a general purpose power supply with a low current fixed 12 volt side and a 2 amp variable side. I had the rig on the 12 volt tap and wound up overheating the regulator! When I connected to heavy duty voltage source the rig worked very well. The 2SC2092s seem to be fine and I have gotten good signal reports so far. By the way, What is "dead bug" construction?

>

Three thoughts about this. Firstly, the toner is meant to be attracted from the drum to the paper by electrostatically charging the paper. Foil will conduct this charge, so the toner is probably going to be deposited less accurately. Secondly, the fuser melts the toner, sticking it to the paper. The foil is likely to conduct heat away from the toner, so it may not adhere very well. Lastly, a fairly strong corrosive will be required to etch the aluminium. Copper reacts fairly readily with FeCl3, being substituted with an iron precipitate. Aluminium has a passivating oxide layer which makes it not very reactive. I suspect some _very_ nasty chemicals would be required - which would cause other problems.

I reserve the right to be completely wrong, by the way...

Cheers,
Theo

My advice is to get rid of it.

Murphey's law says that the next time you are trying to work some rare DX, that lamp controller osc will have a harmonic right on top of the DX frequency.

Rob.

5295. SOME INTERESTING QUESTIONS

Dear friends, I own a ICOM 706.
I would like any of you to send me all information, mods, improvements, and so with the 706. I would like to know also about the interfaces and programs for the 706 and the PC.
I am also very worried about these questions about blowing the 2 metre section up if you have the HF aerial very close to the 2 metre one. I have a vertical antenna for 144 in the same post support than a windom for 80-10metres. Is it any dangerous?. What is the proper distance?
By the way in my building there is a lightning arrestor (pararrayos) post at only 2 metres from my antennas' support. I have always thought that this could be some dangerous though Valencia is not a very stormy city. Anyway, some friends have told me that it is the same dangerous as it would be 50 metres away as a lightning has an action radius of about 150 metres, even a local ham told me to put my windom aerial up to the lightning arrestor mast which is 5 or 6 metres higher than my antenna post. He said is the same danger in the lighning post than only two metres away. What can you tell about all this?.
Will it be enough just swithching off the antenna plugs of the transceiver in case of a storm?.

Another question is, What is the proper high for a HF vertical (WARC Bands 18 & 24Mhz) above the roof of a 14 floor building?. I have one, donnot know it's name but is a trapped one for 10,18 & 24mhz, about 3 metres long (1/4 wave I am afraid). Mine is only at 1.5 metres from the roof and works OK, but many often is beated by the windom one which is only 4 metres from the roof. This is strange for me as I have always read that a vertical is always better than a dipole if that one is not at least at ' wave over the ground. For this theory, my vertical should be better because the dipole windom is only at 4 metres over the ground (the roof of my building), but in many cases the dipole overbeat the vertical. Can anyone explain this to me? What is the best height and number of radials for such a vertical?
I have read many E mail messages of hams talking about the pros and cons of verticals and dipoles, but nothing is clear yet. What is the real truth? Is really any real truth?
Is it true that the windom aerial makes more TVI tan a half wave dipole, for instance? Or than a vertical?
I live in the 14th floor of my 14 stories building. Should I say that my vertical is 45 metres over the ground or just 1.5 ? Should I say that my windom is 49 metres over the ground or should I say 4?
Thank you.

5298. Difficulty with MFJ noise bridge

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-25 00:00:00 UTC
From: kjhales@aol.com
Message-ID: <19970525033000.XAA19842@ladder01.news.aol.com>
Source record: 93777

I am having trouble with an MFJ-202B RX Noise Bridge,
and hope someone can offer some insight.

If I terminate the "unknown" terminal with a 50 ohm
resistor and tune my receiver to 1.0MHz, I get a nice
null (S-meter goes from max to zero). I then tune the
receiver to 2.0MHz. After slight adjustment on the
noise bridge, I can get a null, but not nearly as deep
as at 1.0MHz. Going up in frequency, by the time I get
to 5MHz, I can detect no null. Receiver is an AOR
AR-3000A; CW, SSB, AM all tested with essentially same
results.

The following items were checked:
Fresh battery installed
Power ON
Receiver jack to receiver
Unknown jack to 50 ohm resistor

Does this sound like a defective unit? Defective
operator? Is MFJ equipment typically flakey or marginal?

Thanks for any help.

You might try using a 3-wire cord instead of the usual zip cord lamps use. Then, just inside the lamp, wire 3 caps across the 3 leads. Use 1kv, .001mfd discs, and it should fix lyou up.

good luck.

5301. Two Great QRP Lists

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-25 00:00:00 UTC
From: bry@mnsinc.com
Message-ID: <338842d2.3043064@news.mnsinc.com>
Source record: 93780
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.misc,uk.radio.amateur

I have found two Great QRP E-MAIL lists!

The first is KNIGHT LIGHTS QRP - a group that started in North Carolina, but they allow folks all over to join in on the fun.

To subscribe:

You can send mail to "majordomo@acpub.duke.edu" with the following command in the body of your email message:

subscribe klqrp

Here's the general information on KLQRP:

The KLQRP list is for discussion of activities like technical projects, special operating events like Field Day or expeditions to the NC Lighthouse locations, get-togethers like meetings at member's houses, events like the hamfests, or other special events.

Here is a bit of philosophy from the list manager (Dave, WA4NID). Let me say that I do NOT plan to be a list policeman, in the sense of regulating or moderating the topics of discussion. Everyone is urged to freely post to these lists and suggest topics for consideration. It is hoped that the lists can become one mode of communication for KnightLite members and other interested hams, which encourages camaraderie and progress in amateur radio pursuits of all types. I hope that people will use these lists to keep in touch with the group as a whole, and to arrange meetings with specific members, and to discuss any QRP or radio-related ideas or plans.

==========

The next is probably the BEST QRP list in the world! G-QRP, where you can meet up with the likes of George Dobbs and the boys that STARTED the current wave of interest in QRP, long ago!

To subscribe:

list, you can send mail to "Majordomo@blacksheep.org" with the following command in the body of your email message:

unsubscribe gqrp-l bry@mnsinc.com

Here's the general information for the list you've subscribed to, in case you don't already have it:

Welcome to the GQRP-L mailing list!

This is the informational file for the G-QRP mailing list.

The gqrp-l mailing list was founded by members of the G-QRP club as a focus of QRP activity for QRP operators who have access to the Internet in the UK, and further afield.

The list exists for the discussion of technical matters, QRP operating, QRP events and other QRP-related topics. It is intended to be UK orientated and in this respect is not intended to replace the existing QRP mailing list at netcom.com.

There is a simple but strict editorial policy to keep this list a QRP mailing list, not for it to replace uk.radio.amateur, the rec.radio news groups or any other general discussion forum about amateur radio.

How to join the GQRP mailing list:

send mail to "Majordomo@blacksheep.org" with the following command in the body of your email message:

subscribe gqrp-l

How to leave the mailing list:

send mail to "Majordomo@blacksheep.org" with the following command in the body of your email message:

unsubscribe gqrp-l

How to send mail to the list:

send your mail to "gqrp-l@blacksheep.org"

your mail will then be sent to everyone on the list.

How to receive the daily digests:

If you'd rather not receive each individual message, but would like a bulk mail file sent daily containging all that day's messages to the list, then :

send mail to "Majordomo@blacksheep.org" with the following command in the body of your email

message:

subscribe gqrp-l-digest

Remember that this is instead of receiving the
individual messages, so you don't need to subscribe
to gqrp-l as well.

To stop receiving the digests:

send mail to "Majordomo@blacksheep.org" with the
following command in the body of your email
message:

unsubscribe gqrp-l-digest

Rules on use of the list:

Very simply, please bear these in mind when sending
mail to the list

1. No profanities please, this list may be copied
to packet-radio BBS sites.

2. Messages should be of direct interest to QRP
operators. eg:

a. Technical remarks and discussions relating
to QRP equipment

b. Discussions about QRP operating

c. Announcements of contests, QSO parties etc
d. Discussion of operating achievements
e. Anything else which might be of interest to QRP
operators.

3. Please do not over-quote when replying, most
people on the list pay for their connection to the internet.

4. Whenever possible, reply direct to the sender
rather than the list.

5. Requests sent to the list to unsubscribe from
the list will be ignored! Send these requests to
majordomo@blacksheep.org (see above)

Archives of the list

The list archives can be browsed on the World
Wide Web - point your browser at
http://www.blacksheep.org:8080/gqrp-l/index.html

For great Ham Radio resources on the web, VISIT:

I need help finding a schematic for two old GE mobiles (currently used as local repeaters), especially the wiring for the control head as the controllers are about to be replaced, and the wiring of the old ones us a mess.

the numbers listed on the ID plaques are:

RG56TFS66, or N.P. 243349

and

YG56KJJ66, or N.P. 243349

They appear to be the same radios with different options.

Thanks to all,

Ron, N7TAW

Hello All, I had posted this a couple of weeks ago and got a number of replys. The deal I thought I had fell through, so here is the posting again. You can see a picture of most of the equipment (and me too) on the cover of 73 Amateur Radio Today magaizine, September 1996.

All equipment is good to very good conditon, and all is working FB. All goes as a package only ...

SB-102 Transciever w/ 400 Hz CW filter
SB-600 SPEAKER
SB-610 MONITOR SCOPE
SB-620 SPECTRUM ANYLIZER SCOPE
SB-630 STATION CONSOLE
SB-640 REMOTE (LMO) VFO
SB-650 FREQ DISPLAY
HM-102 WATT METER
HD-3030 RTTY TU UNIT
HD-3006 RTTY 'CROSS-FIRE' TUNER
HD-1481 REMOTE COAX SWITCH
HP-23B POWER SUPPLY
HP-13B MOBILE POWER SUPPLY (NEVER TIRED THIS ONE OUT)
SBA-100-1 MOBILE MOUTING UNIT

QTH is Western New York, and would prefer pickup, so as to demo and save
on shipping costs and hassels. Will ship however, if interested.
Asking $650.00 U.S. (plus any shipping) as a complete package.
If interested please contact Shane, WB2WPM, sbrady@pce.net.
Or evenings (EST) at (716) 675-5797 ...

73, Shane WB2WPM

5321. 30 cartons parts

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-25 00:00:00 UTC
From: Eugene Rippen <soundval@foothill.net>
Message-ID: <3388F79C.2FF3@foothill.net>
Source record: 93800

I plan to take about 30 cartons of parts and small gear to the June 1, 1997 Livermore Swap Meet.

These are mostly some of the 4 building of stuff I bought back in February, 1996. I have now quickly gone through it all. None of this has been to a swap meet before.

I just got rid of my 10 x 20 foot storage unit. I only have my 10 x 30 foot now.. I don't really have room to bring any of this back home, and I don't intend to.

It is all packed and in my flat bed trailer. I have totally repressed what is in there. I will not be able to answer any questions as to what is there. If you build or repair you will no doubt find things you can use.

Gene with white Jeep Cherokee.

5322. fm radio cards

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-25 00:00:00 UTC
From: Jerry McIntosh <jam@comsource.net>
Message-ID: <338885EA.95@comsource.net>

Douglas Wielfaert <marcy@vic.com> wrote:

>By the way, What is "dead bug" construction?

Get a schematic diagram for a simple transmitter, the components and a piece of blank, single-sided PC board material. Working methodically (eg from the xtal osc/VXO towards the pi network) solder components that are earthed to the copper of the circuit board (drill no holes). Then solder components that are not connected to earth to the earthed components as per the schamatic. Where there is need for physical support but no earthed components nearby, use 10M ohm resistors as insulated standoffs, soldered direct to the board.

As you can probably appreciate, this form of construction is best for projects that don't use ICs. If you want to use ICs, use wire wrap IC sockets or mount the stages that use ICs on a small piece of unclad matrix board. You can use PC board pins to anchor these small boards to the main 'dead bug' board.

Provided leads are kept short, 'dead bug' is very good for RF circuits.

5326. Mega Power Mobiles!

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-26 00:00:00 UTC
From: philip de cadenet <phil@two-way.demon.co.uk>
Message-ID: <FHbusJAk9XizEw08@two-way.demon.co.uk>
Source record: 93709

Just because you haven't seen it, doesn't make the earth still flat.
Another gentleman brought up the point of transformers. Most of the
super
power boys that are running MEGAwatts are running ac mobile amplifiers.
This means
that the alternators are taken full field output into step up
transformers
generating anywhere from 3000 to 4500 volts apiece. I have several
customers that are running multiple ceramic tube mobile HF amplifiers,
such as four 8877's, eight
8877's, a single 4cx10,000 and dual 4cx10,000's. you have to remember
that
the rating on these tubes is for continuous duty, not balls out
intermittant amateur
use. They will do much more power intermittantly, especially when driven
well
beyond factory specs. I have customers that are running lexidyne
generators that are used on locomotives. They are double stator designs
that generate 450 amps apiece all day long ! One guy has two of these
and
also uses a 200 amp dc Leece Neville alternator to power his driver amp,
which is 2 X
2SC2290's driving 8 X 2SC 2879's, this is why we lowly cber's laugh at
most hams. The
big boys run, at the minimum, balanced and blueprinted steel crank
350's.
The bearings/crank take a beating with this much of a load on them. I
guess this just goes to show that little boys never grow up, they just
get
more expensive toys.

Thought this would touch your sense of humour.

Phil de G4ZOW/Xtreme mobile, or at least I used to think so, until I met
this guy!

While I can't understand why someone would want to run that much power,
much
less in a mobile, I do understand that nature takes care of it's own.

I would certainly consider being that close to that much RF as "simple
social
darwinism" and the curriosity to be self resolving.

The Handbook is not, cannot, and should not be written at a tenth grade level. There are plenty of introductory books at that level. Barnes and Noble stores carry lots of them.

Twelfth grade or Community College or electronic trade school would be more realistic.

Any High School worthy of the name teaches algebra, geometry and trigonometry.

P = I * V.

From Ohm's law, I = V / R. Substituting to get P in terms of V and R,
gives

P = V**2 / R.

Multiplying both sides by R / P,

R = V**2 / P.

Plugging in the numbers, R = 120 * 120 / 100 = 144 ohms.

> Can someone help me figure out what the impedance transformation ratio
> of such a transformer might be?

It is easily derived if you don't remember it.
See above formula, P = V**2 / Z

Ppri = (Vpri)**2 / Zpri ; Psec = (Vsec)**2 / Zsec.

Energy is conserved, power is energy per unit time, so the power in the
secondary is equal to the power in the primary. Therefore,

(Vpri)**2 / Zpri = (Vsec)**2 / Zsec.

Multiplying both sides by Zpri / (Vsec)**2 to rearrange, gives

(Vpri)**2 / (Vsec)**2 = Zpri / Z sec.

Taking the division inside the exponentiation,

Zpri / Zsec = (Vpri / Vsec)**2

Or in words, the impedance transformation ratio is the square of the
voltage transformation ratio.

Hope that this helps.

Au contraire! :) The term 'dead bug' itself was almost certainly
inspired by the sight of a DIP package glued to a copper-clad board,
resting upside down with its pins in the air.

You can even extend this idea to PLCC chips -- on my bench right now is
a 68-pin Qualcomm DDS chip resting about 1/4" above an unbroken
copper-clad ground plane, supported only by its own ground connections
and Vcc bypass capacitors. It's accompanied by about 20 other support
chips, mostly 16- and 18-pin DIPS glued to the plane with cyanoacrylate
adhesive, but also including a surface-mount 100-MHz DAC suspended just
above the ground plane by the 12 data lines from the synthesizer chip.
Works great.

Admittedly this is a bit extreme -- if I had it to do over again, I'd
save myself the eyestrain and mount the DDS chip with a PLCC prototyping
socket with solder pads. (I wasn't aware they existed when I started
this project.) But I'd mount everything else the same way.

The first unit sounds like an older GE Exec (not the Exec II). If I
recall, this radio may have tube finals. Not sure about the 2nd unit.

5348. AM using "Autotransformer Modulation"??

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-26 00:00:00 UTC
From: bry@mnsinc.com
Message-ID: <3388fc5b.2398409@news.mnsinc.com>
Source record: 93804

Subject: "Autotransformer modulation"
Send reply to: bry@mnsinc.com

Anyone here familiar with this concept and like to discuss it a little?

The idea is that you use an old P-P outout transformer and only use the primary side.

You connect the B+ to the center tap. One side goes to the modulator tube (Can be parallel tubes for more juice if desired. This would be a class A audio power amp stage.

The other side of the xfmr primary goes to your RF final amp stage. You make the idling currents about the same in the two so t hat the NET DC current in the xfmr primary is about ZERO, so that they balance out and the xfmr can handle more power that way.

Now, my friend G3UUR says that this works best when the turns ration on the two sides is about 1.4:1 - so I would think you could use an xfmr with a screen tap on the primary in some cases.

Help me out a little and tell me if this would work.

I have seen designs for small rigs using such a scheme in the old ARRL articles (but not many) and no one seems to have used this scheme for a higher power - say 100-200 watt rig.

Now, I have an audio amplifier that can supply 100 watts using a pair of 807 tubes, BUT the output tranny is no use for modulation xfmr because it only has "70V, 100V, and 120V LINE" outputs which seem to run in the range of about 50-90 ohms characteristic impedance.

I would love to use this brute as an autotrasformer choke mod scheme with a medium power AM final.

Any thoughts, y'all?

Bry, AF4K / G3XLQ

Has anybody had any experience programming the hamcomm interface?
Or know of any Internet resources out there that might give some
clues/tips/information. I can't seem to find anything in that regard, and
I'd like to use it for the project that I'm currently working on.

Most a-m CB rigs use a dual conversion scheme. The most common one
I've seen is 10.695 MHz and 455 KHz. Have you looked into getting a
Sams Photofacts manual on this radio? Drop by your local CB shop
and see if the technician will let you look at the Sams manual, or
perhaps loan it to you to make a copy. Radio Shack can get you the
factory service manual on this radio as well (if you wanna pay that
much).

Not at all. Ferric chloride will attack aluminum
even more readily than it will copper, and you might have
to dilute your normal etchant to keep control of the situation.
As to the rest of it, seems to me to be going to extraordinary
lengths to avoid something that was never much of a problem
to begin with. Photo-etch processes are cheap, easy, and
give excellent results. If you need to make more than a dozen
or so boards, it's cheaper to farm it out to a board shop
anyway.

5352. Re: CB antenna placement

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-27 00:00:00 UTC
From: Jim <jstrohm@taxes.net>
Message-ID: <338AF94E.469@taxes.net>
Source record: 93658

Some often overlooked items of mobile antenna placement --

o How high is the top of the antenna when installed?
(parking garages, low branches, the fluorescent lights at Sonic...)
o How sturdy is the sheet metal where the antenna is attached?
o How hard/easy is it to attach your feed line?
o What else is in the way, like a tailgate or fog lamp?

These should be given greater weight than "what's the best place"
from an electrical standpoint. In this sense, "best" is the highest
point, as close to the center of the vehicle as possible, to provide
the best pattern. If you have a fiberglas shell on your truck, you
may get the best pattern on CB with the antenna in the middle
of the hood. For 2 meter, the roof may be best.

I gave up a long time ago finding the "best" place and instead went
with the installation that was the most secure, easiest to attach
feedline, and easiest to work on or around.

5354. need help with RF speech compressor, SN76514 BM ?

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-27 00:00:00 UTC
From: Peter Shintani <shintani@tv.sony.co.jp>
Message-ID: <01bc6af7$d8ff2f00$6103022b@dell-for-peter>
Source record: 93660

Hi:
I am currently wasting my free time
by trying to design an
RF speech processor based upon a Texas Instruments
SN76514 Balanced Modulator IC. My problem is that the
BM used to recreate the audio seems to have an
asymmetric response. Does anyone have any
experience with the TI SN76514 ?

I use a TL084 as a mild speech clipper and buffer,
a second TL084 has a 300-3500 Hz BPF, feed the
first SN76514 to create the DSB signal.
The local oscillator is a LC osc at 453.5 kHz.
The DSB signal is boosted with a 2SK241
and clipped with two diodes, buffered
with a 2SK125 and fed into a ssb filter.

I am currently using a Murata CFJ455K5
monolithic ceramic filter, about a 2.4 kHz @
-6db response to filter out the unwanted
products of the prior clipping stage.
The SSB signal is then fed into the second
SN76514 BM , sent into a BPF to
remove any residual carrier and noise.

The output of the second BM is distorted.
I am feeding a local level about about 120 mVpp
into pin 5 of both IC's, individually buffered
from the one local osc. The input level to the
2nd BM is about 25 mVpp.
The distortion is apparent even there is
zero compression and and zero clipping.
I am just following the recommendations of the TI
spec sheet. Does anyone have any suggestions ?
Did TI ever release a detailed applications guideline
for this IC ?
Should I forget about using the SN 76514 and
use a different IC for a BM. (I don't have
access to small toroids so I can't make a
discrete BM. I have to use IC's.

Sincerely

Peter

> 73 de Tracy
> tdilyham@rof.net

I doubt the tx just went spurious or the old receiver would have been affected too. I think the hot ticket is too turf the Hamtronics receiver and put a good preamp on the original GE receiver. GE even left a spot in the the front end in which to place a preamp. The reason that the GE receiver was not as sensitive is because it had more filtering, which is lossy. Sometimes adding a hot preamp can cause problems too. If the amp has 20dB gain, you lose 20 dB in selectivity. I suppose everything in life has a trade-off.

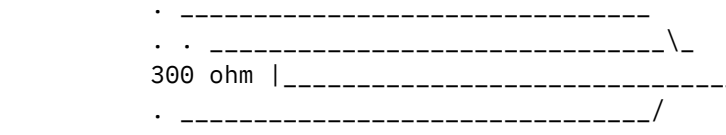
I have used the balun that Admiral used at 100+ watts, and it works
fine, using 4 wire rotor cable (flat like 300 ohm line but 4 wires,
Belden makes it).



Length = 1/4 wave

On the 300 ohm side short the center two conductors, connect to
the outer two. on the 75 ohm side short conductor 1 & 3 and 2 & 4
(no connect at my X) and then connect the coax to center to 1 & 3
and the shield to 2 & 4. (if your are left handed you can reverse
same)

It is very broad band, but use an electrical 1/4 wave to assure
isolation. With a choke balun it will work two octaves.

Have you tried opening the battery pack and replacing the old cells with
new tagged and soldered cells ??
This would cost you about 1/3 of the cost of a new battery pack.

I ahve dine this to many a pack for handhelds and also for computer
laptops.

I have the following sizes and colors of Teflon wire available. All gauges are .07/ft. except #20 which is .10/ft.

Size Color
20 1,4,7

22 0,2,3,4,6,7

24 0,5,7

26 2,6

Limit is 100ft./color/size. Shipping is $3.00 for any amount.

Thank you,
Dale

Can any one help me to a site on the net that has a simple stepper controler on display including the parts i need to buy.

I want to build a remote antenna controler and would like to use some stepper motors from a old printer to rotate the C's and windings.

So if you know any thing that could help me please send me a reply .

Hope to here from you !!!!!!!!!!

Aluminum can be etched with Ferric Cloride so no new and more dangerous
chemicals are needed.

No comment on the rest of the process!

Bob

Anaheim Automation has a stepper controller which is pretty inexpensive, they are in Anaheim, CA.

To make a stepper move, all you need to do is switch two windings in the motor, for example when you energize the first winding your at 0 deg. now energize the second winding and your half way between 0 deg and 2 deg. now turn off the first winding and voila you move to 2 deg. The next part is a requires a little more, you must invert the polarity of the first winding and then do the same with the other.

If you can build yourself a regulated supply to not exceed the current rating of the motor, the rest can be done by simply turning on power transistors to the windings. In the electronic trade magazines I see many ads for cheapo controllers.

On the other hand, if you still have the printer complete you already have the driver! It will take some experimentation but if you put 5v (use a 1k to drop) to the different pins of the controller you'll make the motor move.

About 5 years ago I got a replacement directly from Drake, can't remember what it cost, but it was not identicle to the original switch in that it had 3 positions. When wired in and pushing to "on" the first "on" would not turn amp on, had to push again to go to the next "on". Hey, it works. They may have the correct ones in now.

Not at all. Ferric chloride will attack aluminum
even more readily than it will copper, and you might have
to dilute your normal etchant to keep control of the situation.
As to the rest of it, seems to me to be going to extraordinary
lengths to avoid something that was never much of a problem
to begin with. Photo-etch processes are cheap, easy, and
give excellent results. If you need to make more than a dozen
or so boards, it's cheaper to farm it out to a board shop
anyway.

I'm on an email-only account and cannot read this NG so *please*
eamil me any comments you might have regarding the following:

Hi Folks. I've converted a RS TRC-415 cb to 10m (changed the 10.240 MHz
xtal to a 10.635 so that now ch1 = 28.01 MHz, ch2 = 28.02, ...).

My intention was to use this for CW, and I found a spot to splice
the key into (between the xtal oscillator and the driver stages)
that gives pretty clean keying.

Now, how to add a BFO? If its rcvr had the traditional 455 kc IF,
a BFO would be easy to install. But without a schematic I have
no idea what this sythesized rig uses for an IF. Any ideas?

I'm on an email-only account and cannot read this NG so *please*
email me your comments.

Thanks in advance, and 73,
Jeff KH2PZ / 7

Get/rent a spectrum analyzer and see where the spurs are coming from. Could
be that you could retune the LPA in the exciter or the PA in the amp and "put"
the spur(s) somewhere other than the receiver frequency. Or, you could have
a component ready to die. GL

5381. UHF Repeater Desense Problem

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-27 00:00:00 UTC
From: tdilyham@rof.net
Message-ID: <N.052797.113654.99@rof.net>
Source record: 93753

Howdy,

Hoping someone out there might be able to shed some light on or suggest a solution to a problem I am having with repeater receiver desense.

Recently, I decided to give our 449.725- GE MastrII Rack Mount Deck (what I thought to be) a better set of ears. The old MastrII UHF Receiver with .5 microvolt + plus receiver deck was replaced with a Hamtronics R451 Receiver. The new receiver is contained within an RF Tight pressed fab aluminum box with tight fitting cover mounted within the existing receiver deck (on the drop lid) of the MastrII Base/Repeater Chasis. All wires (B+, COS and Spkr Audio) use feed through caps. The antenna connection still uses the stock grey RG-174u RCA cabling from inside the receiver deck to the rf tight enclosure (which is enclosed in the old receiver's compartmented cavity covered by yet another lid).

The GE Exciter (within the drop lid in the lower partition) and GE 30 Watt PA (contained within the swiss cheese box attached to the heat sink on the back) are the only GE OEM parts being utilized. Controller is an MCC RC-100 mounted on top of a slide in card (the old GE decommissioned COS relay card) located in the card cage (directly above the PA). GE fans will recognize this as the place where the 10VDC regulator resides.

The problem: RECEIVER DESENSE! When the PA is off, reception is great! Full quieting even on the weakest signals (every repeater owner's dream!). Turn on the transmitter and it all goes to hell (every repeater owner's nightmare)! Given the extent of rf sheilding, feed throughs, and specific repeater design by GE, etc., I am at a loss to figure out what's wrong. The GE receiver did alright--but nothing to write home about! Of course, it had a 7 stage helical front end. But Hamtronics claims a -100dB figure with use of an 8 pole crystal filter. Duplexers are DB Products 80+ dB full size rack mounts. I don't believe these are the culprits since they worked before the ear transplant.

Now, I'm thinking PA? Could the PA be blasting spurs directly into the R451? Or what else could be responsible? Might anyone out there have had similar experiences or possibly be able to give me a clue as to what might be happening?

I'd welcome any help or advice. This one's got me flustered...

What happens if the IC fails or you need to (temporarily) borrow it for another project? In either case, you would need to unsolder all the components soldered to the IC (regardless of whether it's in a socket or not) and use some pliers or a lever to prise the chip off the board.

As one who is always pinching ICs from projects to use in others (especially NE602s :) all this is too messy for me, and with my typical hamfistedness, I'm likely to break something in my attempt to get the chip off the board.

I just built a remote control to tune the capacitor of my homemade
magnetic loop antenna. I used a stepper motor that was part of a 5"25
floppy disk drive (for moving the r/w-head). Try getting a drive
which is out of order - the stepper motor will probably still work.
This kind of stepper motor can be controlled by an SAA 1028. You
only need very few additional parts. Ask for the IC's data sheet.

While you could down-convert the 2 meter band to some 4 Mhz portion
of the 88-108 Mhz FM band, the results would be disappointing. FM
broadcast receivers are designed to demodulate much wider-band
signals than used by amateurs. I suspect the distortion would be
awful.

Also, the steps would be too far apart with digital tuning.

That said, I wouldn't be the least surprised if some ambitious
ham didn't find a clever way to make this work. :-)

>no idea what this sythesized rig uses for an IF. Any ideas?
>

To check the IF of the equipment you need an RF signal generator capable of coverage of from below 400 KHz to 30 MHz or so. Connect a piece of wire to the output of the signal generator. With the CB receiver on (say channel 20, preferably with covers off), sweep the generator over its frequency range. If you hear a carrier try switching the channel change knob to see if it disappears. If it does, keep tuning the generator. If the carrier can be heard on all channels, you've found the IF (or a subharmonic of it) with your signal generator. To check this, it's probably a good idea to start with the sig gen on its highest frequency and tune down - then you will pick up the first (high) IF first and the second (low) IF next. Common IF freqs for CBs are 10.7, 7.8 & 455 kHz. If you find that the carrier can be heard across two channels at settings of the signal generator that are not harmonically related, your radio probably has two or more IF. And, you can use the sig gen as a temporary BFO until you finish building the permanent unit.

Hello!
We have a couple of specials this month:

TEKTRONIX 465M 100MHz Oscilloscopes, all reconditioned and
calibrated, 120 day warranty shipping free in the USA, $465.00 each!

JAN 6186W, equal to 6AG5WA, sharp cut-off pentodes 7 pin miniature
made by Philips in the USA 1986, NOS, individual boxes, 8000 available,
$0.10 each, shipping in the USA: 1 - 199 $3.00, 200 or more shipping free!

For more ELECTRON TUBES (both new and/or used), various ANTIQUE RADIO
COMPONENTS or ELECTRONIC TEST EQUIPMENT, please E-mail

sales@emodus.com

For a complete list. Thank you! Dealer inquiries welcome!

No need to go any farther than what's above. It contains the reason for your problem. Personally, I have found the GE Mastr II receiver to be one of the best ever produced. What you should have tried is a nice medium gain RF preamp infront of the GE RX. That Hamtronics may have lots of sensitivity, but it lacks in Selectivity by leaps and bounds compared to the MAstr II. Those front end helical resonators on the GE are what kept your TX out! The Hamtronics has nothing like it. That 8 pole filter you cite for the HAmtronics is down the line in the IF and does nothing to reject adjacent frequency coming into the RX front end, where it gets amplified.

My recommendation, go back to the GE and try a nice quality preamp. Also, you may have a duplexer tuning problem that didn't manifest itself until you added a RX with more gain. If you get desense with a preamp in front of the GE, do some serious duplex tuning.

Announcing NEW
Ham Radio.FAQ

This is the second generation of the original file that was
a regular USENET posting entitled

"rec.radio.amateur.misc Frequently Asked Questions"

The NEW Ham Radio.FAQ is a HyperText document that is on the
WWW and it contains 3 chapters plus hundreds of LINKS to radio
related sites!

1 - Introduction to the Ham Radio.FAQ
2 - Amateur Radio Organizations, Services, and Data Sources
3 - Amateur Radio Advanced and Technical Questions

Please provide a copy of the Ham Radio.FAQ to any new or
soon-to-be Hams that you know or share with them the URL to this
site:

http://www.mv.com/ipusers/wd1v

Send me an EMAIL <or packet with your Email address> if you want the
FAQ text file sent to you as an attached <120 K> file with the words
"HAM FAQ" on the subject line.

Send me a formatted disk with SASE disk mailer if you want the
FAQ text file sent to you on disk. PC or Mac are fine.

There is an informal group of amateur radio operators that use Macintosh computers called "Macnet" with > 800 members world-wide.

We stay in touch with each other via packet & Internet and we have a HyperCard stack that tells the story of each of us called "Macnet Roster" that list

o CALL SIGN @ HOME PBBS
o FULL NAME
o Street ADDRESS
o CITY, STATE, ZIP
o INTERNET ADDRESS
o MACS USED
o RADIOS USED
o SOFTWARE USED
o PASSIONS
o COMMENTS

Macnet members can then communicate with one another directly or use our Macnet Moderated Mailing List to pose comments or questions to all of us on the Net.

To join Macnet, put YOUR INFO (via EMAIL or via disk using TEACH TEXT on a formatted disk in a self addressed and stamped disk mailer that is in a large envelope clearly marked "ROSTER").

Or connect to our home page via the WWW http://www.mv.com/ipusers/wd1v

-------<sent to all new Macnet Subscribers & Macnet Roster Updates>---------

Welcome to Macnet!

A trip to my home page also reveals there are many superb files and programs for amateur radio operators that want to use Mac computers. See more details in January 1997 QST, page 100. http://www.mv.com/ipusers/wd1v/

* Ham Radio Test Simulators - where you can go from Novice to Extra Class practicing the actual tests right on your Mac! Check out the info on the new NO CODE license or scramble your neurons and learn Morse on the Mac too!

* Macnet Email Reflector - send an Email to all Macnet users on the Internet.

* Macnet Roster - a virtual "Who's Who" HyperCard stack with > 800 entries giving the names, addresses, phone numbers, of radio operators all over the world that are using Macs. Check out their projects and

their passions and put a design on your Mac Radio future. See what neat things are being done with Macs and Ham Radio!

* Mac Ham Radio Software Listing - as the name implies, its "The List" of the latest - much of it with FTP links so what you see is what you can get your new programs with just a click.

* Ham Radio.FAQ - compiled on a Mac with a lots of links to great Mac FTP sites for radio, electronic engineering, and similar data.

What happens when you remove or disable the clipper, so
you just create a DSB signal, reduce one of the sidebands,
and demodulate the result?

You need high Q filters on both transmittter and receiver. All transmitters produce broadband noise and nearly all receiver front ends will saturate without them when presented with 0 dBm or higher inputs.

An RF/IF clipper requires *two* IF filters, one between the first modulator and the clipper and the second between the clipper and the second modulator.

The purpose of the first IF filter is to remove the image frequencies so that they do not get into the clipper. If this is not done, odd-order harmonics are generated in the audio output. A close scrutiny of the various mixing operations involved will show why this happens.

The 1996/7 ARRL Handbooks, chapter 17, show the correct block diagram. The 1995 block diagram is incorrect. As the author of that chapter. that oversight was my error.

I would also suggest eliminating the audio clipping because it is redundant.

You might also like to read my article in the Winter 1997 edition of Communications Quarterly, which uses a different simple approach.

From: owens@stout.atd.ucar.edu
Message-ID: <5miccr$7l3$1@ncar.ucar.edu>
Source record: 93679

I'd like to build a PIN diode T/R switch at HF (1.8-30MHz) at
the 1.5 KW level.

Alpha Power Inc. uses this type of switching in their famous
line of HF linear amplifiers. Does anyone out there have an
Alpha amplifier that would volunteer schematic and PIN diode
information that would help in building this type of T/R switch?

Has anyone built (successfully) a PIN diode T/R switch that
works at the 1.5 KW level? If so, I'd like to hear from you.

Thanks & '73, Chip Owens, NW0O, Boulder, CO

Trying to get a HE45b up and running, but having some trouble. Any comments/suggestions would be great...

A 7868 pentode is the modulator and audio amp. The final (plate modulated) is a 2E26. Problem is, no modulation. I have to whistle very loud into the
mic to get any indication that modulation is taking place at all. I have checked the mic and tested all the tubes, and all appear to be fine.

One outstanding symptom is that the 7868 (modulator) gets VERY HOT, alarmingly so, even when I am not attempting to transmit at all. I checked the tube-socket voltages and they seem to be OK, in the ballpark. The rig works fine in receive mode, incidentally, so as an audio amp the tube is working properly.

When I first got the rig there was a strange squeal (intermittent) upon adjusting the tank (output) capacitor for peak power. The squeal seemed to be coming from the 7868 or nearby.

Now I don't even get the squeal, and the relative transmit power seems to be greatly reduced compared to what it was. I used to get a half-scale reading on the meter when keying the mic and peaking the output, but now about 1/5 scale is the best I can get.

The manual states that the meter should fluctuate as you speak, and I have not had this happen at all. A loud whistle will make the meter reading drop, but only a very tiny bit.

One final note -- now when I key the mic the output hits its max value, but immediately falls off over the first few seconds.

I replaced the modulator 7868 tube recently, but the rig still does not behave as it should (there was no difference).

I would be grateful for any suggestions. The tcvr is in excellent cosmetic condition and the components do not show signs of failure, burnout or leaking, so far as I can tell. So... ??????. Anybody got any hints?

Many thanks,

JWG N1AEP Freeville, NY

5404. Re: converting cb to 10m

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-28 00:00:00 UTC
From: Michael Black <blackm00@CAM.ORG>
Message-ID: <Pine.GSO.3.94.970527235403.12526B-100000@Ocean.CAM.ORG>
Source record: 93683

Are you sure the thing is actually working with the new crystal?

I don't know that particular set, but I've seen schematics for
CB sets and the 10.240 crystal is used in a number of places.

Divided down, it is the reference frequency for the sythesizer. Thus,
if it's changed, the channel spacing changes. 10.240/1024 = 10 KHz.
10.635/1024= 10.385 KHz.

It may be used as a local oscillator (either directly or divided by
2 I think) to mix the output of the VCO down to a lower frequency
before the signal enters the divide by N chain.

If it's a dual conversion receiver, it's used as the second local
oscillator to move from about 10.7MHz down to a 455 KHz second IF.

I thought these were fairly standard, though there were exceptions.
There were also variations, if I recall correctly. More recent
CB sets used PLL IC"s that did not allow for easy modification.

Depending on the circuit, changing the 10.240 MHz crystal will
not only change the channel spacing, but also, mess with the IF
chain. The combinations of the oscillators will not line up
the right way, and also if ceramic filters are used in the
receiver, the desired signals will be out of the passband.

As I said, I don't know this rig so perhaps the 10.240 MHz xtal
is used in a different way, though it does seem odd to see that
specific frequency used if the familiar scheme is not used.

As far as the IF frequencies go, you may be lucky. Open the rig
up again, and look for ceramic filters. Look for something that
looks like a ceramic capacitor, except it has 3 leads. If it's there,
it should be marked with a frequency, and chances are more than likely
that it's 10.7. If it's a cheaper rig, it may not have that filter, or
it may not even be double-conversion. If it's a more expensive rig,
or it's an SSB rig, then the first filter is bound to be bigger and
will jump at out you when you look inside. Hopefully it will have
a frequency marked on it.

It's most likely that there is an IF at 455KHz (or perhaps 450KHz),
whether it be the only IF or the second IF frequency. While in
years past some CB sets did feature Collins mechanical filters, it's
more likely that the filter at this frequency is ceramic. All of
those that I've seen are in a plastic square or rectangular package,
colored orange or green. The number of pins depends on the particular
filter. Again, if you're lucky it too will be marked with it's frequency.

5407. Help with Transistor Identification

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-29 00:00:00 UTC
From: georgie@aztec.asu.edu
Message-ID: <5misd3$nv8@news.asu.edu>
Source record: 93686

I have a transistor I need to replace. It is about the same size
and case as a 2N3053.It has RCA on the top. Below the RCA is, what
I imagine is, a date code: HY 7901. Above the RCA is a number
60352. I imagine this is the identifying number but I can't find
it in my catalog. Can anyone help? Please Email. Thank you.

Um, excuse me folks. I read a handbook cover to cover in seventh grade. I understood most of it too. And I was a C and D student too. By tenth grade I already was reading things like the CET exam book. I would be suprised if the handbook was written to 10th grade level, my guess is 9th grade. By the way, the U.S. Air Force only requires that it's enlisted corps read at the 9th grade level and we deal with electronics far more advanced in operations and maintenance than anything in modern amateur radio.

The Handbook is not, cannot, and should not be written at a tenth grade level. There are plenty of introductory books at that level. Barnes and Noble stores carry lots of them.

Twelfth grade or Community College or electronic trade school would be more realistic.

Any High School worthy of the name teaches algebra, geometry and trigonometry.

5415. HF VERTICAL & DIPOLE ANTENNAS

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-29 00:00:00 UTC
From: jorgegc@mundivia.es
Message-ID: <338dab7b.122284@noticias.mundivia.es>
Source record: 93694
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.antenna,es.rec.radio.amateur

Hello Friends !

My name is Francisco and first of all let me thank you for reading this message.
I have some questions and doubts about HF antennas, so if you can help please send me a message.
My antenna instalation nowdays is a windom antenna that I made myself with a 1:6 balum, which is 41 metres long and it works ok on 80,40,20,17,12 & 10 metres. It is at 5 metres over the roof of my 14 floors building. I also own a commercial vertical for WARC bands but I donnot know it's name or brand. It has a first part of aluminium for 12m, after that a coil and another part of aluminum for 17m and then another coil and another part of aluminum for 30m. I would like to know which antenna is it, maybe it is not difficult to know as there has to be not many Warc vertical in the market. I have took the last vertical part of aluminum off, as i donnot expect to use the 30 metres band, and I have taken this off to make the antenna shorter. (I guess it will not modify it's caracteristics on the 17 and 12 metres band).
I took this last part off also because I had to repair the first coil (the one for 17 metres) because it was broken. I glued the plastic part with epoxy glue and I soldered the coil to the aluminum part, anyway I thought it has been not a good solution as I found that the aluminum did not soldered very good. Maybe there is another good solution to repair it in good conditions. Due to this repair I took the last part of aluminum off to make it shorter and maybe more resistent to wind effect. I have also put nylon cord to the antenna.
I have put the antenna just at 1.5 metres over the roof with two radials, one for 12 & one for 17metres band (1/4 wavelenght ground radials made of copper wire). They are parallel to the ground, I mean they are 90° to the vertical element. I do not know if I will notice much improvement if I put the antenna to 3 metres over the ground and if I put two or three radials for each band, also do not know the angle between the vertical radiator and the radials.
By the way I thought that the vertical was going to work better than the windom, but several times I hear stations with the dipole that I can not hear with the vertical. Only from time to time the stations from USA are a little bit stronger in the vertical, but I wish it could work better on Dx than the windom dipole.
I also wonder what could it be the difference in performance in the 17 metres band between the coils vertical and a ° wave monoband vertical for 17 metres. Will it be too much?
Another question that I have is, What is the difference in performance between a windom antena and some doublets ° wave dipoles antennas for

the 20,17,12 and 10 metres band? Will a wave dipole outperform the windom so much?
Please tell me also which vertical can you recommend if I live in a place affected with high winds in some months of the year and very close to the sea (I can see the beachside from my bedroom window. How about the magnetic antennas, which first of all seem very expensive?
What is the proper distance between a HAM antenna and a lightning post arrestor? What will it happen in a stormy day?
73S and thank you in advance for your answers.

$65 + shipping..

------------------- F L A S H L I G H T S ---------------------

4-D cell (2x2 style), krypton bulb. In box, never used.
$5 + shipping.

6-D cell multifunction lantern. Sleek tubular style with
bright incandescent light at end, 6W fluorescent bulb
along bottom, and flashing red and yellow on top. Also
has electronic sonic alarm that can be switched on with
the flashing lights. In box, never used. $12 + shipping

3-C cell Eveready worklight-style. Bright yellow with
hook for hanging, frosted bulb to diffuse light over area.
Unused, but no box. $5 + shipping

Batteries NOT included.....

COCA-COLA caps. Red cloth, white lettering. New.
$8 each + shipping. Only 9 available.

..... FOR YOUR DRIVING PLEASURE .....
1929 Mercedes SSK kitcar on VW chassis. Just completed, never titled.
Yellow, with brown fenders and running board, tan convertible top, side
curtains, and tonneau cover. Gold trim instruments.

COBRA 18-ULTRA CB ---- 40 channel, pushbutton tuning, with 3
NOAA weather channels. Includes microphone, but no mounting
hardware. $ 39.

LEXMARK/IBM PORTABLE PRINTER 5183 ---- powered by rechargable
battery or AC wall adaptor (included), this printer is only
11.5" x 3.5" x 2", and weighs about 2.5 pounds with battery
in place. Using silent thermal print head, it will print on
either thermal fax paper or on regular paper using the enclosed
thermal transfer ribbons. Very quiet in operation, and because
it runs on a battery, it is completely portable, for use with
laptop computers anywhere. Includes parallel port cable. $89.
.
ANADEX WORD-SCRIBE PRINTER ---- heavy duty dot matrix printer.
Multiple ports, but no literature so only parallel port in use
now. Tractor or friction feed. Fast, good quality; 17-inch
platten. $ 15
.
add shipping to all prices.
if interested, leave e-mail...

Hello Paul and Bill,

I too read radio literature at the level of ARRL Handbooks in Jr. High School.
But that was Jr High THEN (1950's) not Jr High NOW. With the general dumbing-down of U.S.
grade school education over the past 3 decades (10 percent decline in SAT scores
in spite of quintupling the constant-dollars spent per student!), it is not surprising
that both the ARRL Handbook and QST in general have likewise been dumbed-down. (The ARRL matches

the level of material to their target audience; that is how they stay in the publishing business).
We have folks who are functionally illiterate in their native (English) language graduating
not only from high school, but apparently some colleges too.

73,
Don, W6JL

Tube Manuals, Tube Substitution books, Service Manuals, QST magazines, much more from the 30's, 40's, 50's, 60's. Now over 1600 different tube types in stock - Contact Rog42@aol.com and ask for an E-mail copy of my latest offerings on RADIO list - #528-T. - Approx. 100 new publication titles just added to the list.

5421. Linking two 6M repeaters

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-29 00:00:00 UTC
From: John Welton <John_Welton@unc.edu>
Message-ID: <01bc6c2c$553db700$d5e70298@JWELTON.UNCH.UNC.EDU>
Source record: 93700

We are looking at linking two 6m repeaters, one in the Western part of NC in the mountains at ~ 5,000 ft (proposed) and one in central NC up on a tower at ~1300 ft HAAT (Chapel Hill 53.45/107.2pl - to be implemented shortly). Distance between the two is ~140 statute miles with nothing of interest in between.

What would be the best way to link these two machines on a continuous basis?

1. would a remote base at one of the sites for the other repeater cause interference/desense at that site? (we don't have freq coordinated yet for the mtn repeater so can't say what the freq spread would be)

2. if # 1 was used at the mtn site, we could put in extra band reject cavities and a beam for the link to CH (should be no problem with space), the opposite would be impossible at the Chapel Hill site since there's no additional room for cavities up on the platform)

3. should we consider a simplex 220 dedicated link with beams at both ends - two extra radios/ant (anyone know of a reasonably priced continuous duty 220 link RX/TX). The distance is probably too far for a 440/430 link.

4. could find some half way point and cross link the two repeaters.

5. any other options/opinions??

I have, in front of me, The Radio Amateur's Handbook for 1973.
In my opinion, it's just as dumb as the 1997 edition of the
same book. There's less of it, too.

and how many people respond to the article ? anyone have done this
thought of thing ?

>STEP (4)
>You are now in business for yourself, and should start seeing
>returns within 7 to 14 days. Remember, the Internet is new and
>huge. There's no way you can lose.

there's no way you can lose your mind huh ? keep posting your name +
address. you will become pretty famous !! well... in a bad way.

The dumbing-down of our whole education system for 4 decades
now is becoming very prominently apparent as we compare to achievements
in other nations. The final cap is that today there are more Master's
and PhD candidates from off-shore in our U sytems than US born
candidates.

You can bet that this demise pervades from elementary to
middle school to high school and colleges. Brought about by the
"experimental" educators since WW II at every turn! And our
"friendly" National Education Association.

5433. Racal RA1772 Receiver

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-30 00:00:00 UTC
From: john.taylor@emelec.co.UK
Message-ID: <9705301432.AA02043@emelec.co.uk>
Source record: 93613

Can anyone help with locating source of service manuals for the RA1772?
Three of us, UK amateurs, have aquired these receivers and all have some
sort of faults - with mine, although the "vfo" appears to operate, and the=20
frequency
display changes, the "vfo" seems disconnected from the rx as the rx=20
frequency
does not change. Everything else seems OK - antenna noise, and even the odd
station heard on HF at night, but cannot alter the rx frequency - any=20
ideas???

Thanks on behalf of G4ZHG, G7MUB and G8DYK,
John, G8DYK

john.taylor@emelec.co.uk

Shortwave pirate chasing actually has quite a following. George Zeller publishes a direectory each year of pirate stations that he's heard. A lot of them are one-time broadcasts, but some are quite regular. Some even list mail drops that you can send an SASE to for a QSL.

I personally have no problem with pirate stations. They're operating outside the U.S. amateur bands, so they're not interfering. Shortwave broadcast stations aren't found on this frequency either. I'm sure they know the illegalities and the risks, so please spare the lectures.

Hi,

Is there somebody who has the pin assignments of plug 14 of this old (at least more than 10 years) R&S receiver. The plug is normally attached to the power-supply, which I'm missing, and has two rows of pins (labeled 1-8A & B). Any description on what comes out and goes in would be great. This would help me in building my own power-supply.

73s, ON1DJU

Hi Brian,

WOW, Amtor obsolete? Funny, I use it almost every day. Actually gets
through better than Pactor
for weak sigs/dx, due probably to the shorter burst length and simpler
5-bit+ 2-parity constant-ratio code.
They knew what they were doing when they designed SITOR, for plain-text
use on HF cicuits. That matches
real-time ragchewing very well. I think if you read advertisements,
and product reviews in QST and CQ, you
can get the impression that Amtor is "obsolete". Not so. There are
many cases where "newer" ain't
necessarily "better", but one seldom hears about them in magazines which
rely on advertising. I have
three Amtor controllers, and I would not part with one of them.

GL, I am sure you can find others who are willing to give up theirs...

I'm not quite sure what Jacqui was talking about, but the unofficial
home page for the HamComm digital communications program (but not including
FAX) written by DL5YEC, can be found at:

http://www.accessone.com/~tmayhan/

There are lots of tips for using HamComm as well as plans for building
an improved interface.

5445. TH-75 A help needed

Newsgroup: rec.radio.amateur.homebrew
Date: 1997-05-30 00:00:00 UTC
From: Michael Gladu <mgladu@warwick.net>
Message-ID: <338F0B90.7DCB@warwick.net>
Source record: 93625

Greetings all Kenwood TH-75A owners and experts,

I recently aquired a used Kenwood TH-75A and would like to ask a few
questions about it. From looking at the schematic, I was curious what
D2, D3, and D4 do exactly to the operation to the radio.
I would like to modify this handheld to transmit up at 470 to 480 MHz.
Is this possible ??? Have any of you documented what each of these
diodes does ??? I used to own one and used it in the 450 to 460 MHz
band for commercial 2-way transmissions at the 2-way radio shop I used
to work for. I know that I had to "tweek" the UHF VCO.
Also, I would be interested in purchasing the service manual for this
radio. Does Kenwood still sell service manuals ??? Any one have one
they would like to sell ???
Thanks for any and all info. You can email me directly at:
mgladu@warwick.net

>
>5. any other options/opinions??
>

A possibility could be to install a normal 10m, 2m, 70cm or 23cm repeater about half way between the two six metre repeaters. Then use 'off air' linking to link the six metre repeaters via the two metre repeater. This could entail having a 2m/70/23cm transmitter/receiver at each 6m repeater site. The benefit of this is once you have your 2m or UHF repeater frequencies, you don't need additional frequencies for linking. As with any off air linking, there is saving of equipment - there is need for linking equipment at only one end to link two repeaters, and only two sites to link three repeaters (as we are effectively doing here). If course, if you were linking (say) a 6m repeater to a 2m repeater, you wouldn't need an additional repeater half way in between, as the repeaters to be linked are on different bands.

WWW Message Board Experiment

Folks,

May I engage your services for an experiment...

As you know, I set up a "Personal Web Server" on my
home computer running Win95. Previously, the server
had only a copy of my web page...

But, now...

I have taken the mirror of my home page off and installed
an automated message/discussion group faility called aptly
"Short Circuits"...

Please go to my home page http://www.qsl.net/k7on and click
on the rotating arrow and while I'm connected you'll be then
connected to my personal server where you can access the messages
entered by you and others.

It is threaded and resembles a Usenet newsgroup, but will not
be spammed as it is not connected to the Internet by a static
IP address...(this is part of the experiment, BTW...)

Please give it a shot!

I'll be watching for messages on there and I've put 2 already myself.

73, Brian http://www.qsl.net/k7on

Has anyone ever succesfully reworked or modified Bird wattmeter slugs
?
I'm wondering what is involved in changing the power rating or
frequency range within a slug (or if it is even feasible) ?
Not having ever owned a Bird wattmeter (but considering the purchase
of one) I have no knowledge of the internal workings of the slugs
other than that they are basically tuned pickup sensors that drive
the meter.

Many thank !

I disagree that The Handbook has been dumbed down. Compared with the
1995 or later editions, the old books are a terse idiosyncratic
patchwork. The newer version covers more current technology and
theory to a greater depth than the old one.

It is a shame that they wimped out on the math. But that's a general
problem. At least in the US, mathematics has become the defacto
monopoly of the mathematicians and mathematics educators, (the people
who seem to have done the worst job of it). The general book publishing
industry has virtually no materials that I've seen that introduce or
can serve as self study materials for anything more advanced than 10th
grade. It's either trivial or textbooks (and mostly textbooks that are
designed to require a teacher).

The reason AMTOR may perform better is due to the lower baud, 45.5
versus 100/200 for PACTOR. Shannon tells us we can trade speed for
SNR. A *good* PACTOR implementation with memory ARQ will still usually
show a greater average error free throughput than AMTOR (not all PACTOR
implementations are good, tests have shown up to a 2:1 variation in performance
depending on the brand of the controller).

The superior FEC of PACTOR II, Clover II, and GTOR make them greatly superior
to AMTOR. And PACTOR II and Clover II can adaptively slow baud to even lower
rates than AMTOR for the really tough conditions (and their implementations use
DSP to allow them to take maximum advantage of that adaptive ability). GTOR's
fixed higher baud, and lack of adaptive DSP, make it fall apart at higher signal levels
than the other two, but it is still usually better than AMTOR.

AMTOR may not yet be obsolete, but it *is* declining in popularity as
the better methods are coming into wider use. Aside from its lesser
performance ability compared to the best available methods, its lack
of support for a full modern character set has reduced its popularity too.
It is far from dead, but many of the newer controllers which can do it can
also do the better methods, so its appeal is declining as those newer
controllers penetrate the market.

That's true, Don, but how many of them are trying to be hams?

You have to be careful with this "dumbing down" business. Yes,
average SAT scores have declined, but in the 1950s only 10% to
15% of a high school class *took* the SAT. And they were the *top*
10% or 15% too, those who were college bound.

Today nearly *every* high school student takes the SAT, thanks to
college becoming something nearly all students are expected to attend
rather than being intended only to serve the "best and brightest". The
Bell Curve assures that this near universal testing will naturally lower
the average score. But the top 10% to 15% are still scoring well.

So declining average scores don't represent a dumbing down. Instead
they represent a dilution *of the measurement*, and that has very different
implications. When you discount those taking the SAT who are destined
for the manual trades and look at the top 10% to 15%, you find about the
same relative number of bright and sharp students as in the 1950s.

Indeed, thanks to the extra funds and effort poured into some school
districts, perhaps 30% to 40% of today's students are scoring on a par
with the top 10% to 15% of the 1950s. But on the bottom side are students
whose only score is due to putting their name (sometimes misspelled)
on the top of the answer sheet. These students *didn't take* the SAT in
the 50s. That drags the average score down today, but it doesn't represent
a dumbing down of the population. Those stupid kids existed in the 1950s
too, they just didn't take the test, and usually didn't graduate from high school
either.

High school graduation requirements have been lowered in order to graduate those dumb kids, and college entrance requirements have been lowered in order to admit those dumb kids, but those dumb kids were there in the 50s too, they just didn't graduate high school, take the SAT, or go on to college.

The bright kids are just as bright today as they were in the 50s, and exist in about the same, or perhaps somewhat higher, numbers than they did in the 1950s too. They are the natural audience for the Handbook, not the functional illiterates. That's why dumbing down the Handbook is a tragic mistake. It devalues the Handbook for those capable of benefitting from the information it contains. But dumbing it down doesn't benefit those too stupid to appreciate it anyway.

#1 All coax needs to be double shielded or 100 % shield type of coax from duplexers to transmitter and to recv. #2 The Hamtronics is not the better choice for a receiver. #3 The duplexers need to be checked for rejection on the receiver side of the Tx Freq. #4 Sometimes the antenna match can cause problems. With better receive sens. all of these need to be checked. 73, Bill

5465. Planar Data Wanted

Newsgroup: rec.radio.amateur.homebrew

Greetings,

I am looking for technical information (characteristic curves,

specifications, mechanical drawings, application notes, etc) for the

familly of ceramic planar triodes made by GE. Some example type numbers

are : 7296 7462 7588 7625 8081 8082 8083

Please email or post anything you feel may be of interest, thanks in

advance.

Hi,
Thanks for reading this.
I'm Jean-Phi, in LIMOGES, Middle FRANCE loc: JN05PT
Since more than 1 year via packet or Inet, I' looking for QSO Jim
McLellandd,
WA6BQU for questions about the DCTL antenna on 80M :
In the French version of CQ Magazine, May 1995, there is a description
of this "Distributed Capacity Twisted Loop" for 80M
There is no formulas for calculate an other version E.G. 40, 30 or 20Mtrs
In the article, it's gave the length of :
LL : 8.534M (main & twisted loop)
LC : 0.76 M (Open Loop, capacity)
LZ : 1.37M (Impedance Adapation Loop)

If somebody have info, please give me !
i am living in a flat, at the 7th floor, and the roof is at the 13th !
and i have no possibilty to place any antenna at the top of the building.
Perhaps, your info will give us the possibility to do QSO on HF !

To Jim, WA6BQU : Congratulations about this antenna. Reading the article
give me a kind of dream !: I will operate my HF TRX (IC725) very soon !

To all : Best regards and wishes to you and your familly, 73's and Tks Agn.

And sorry about my approximate English ! I hope it's unterstandable.
I understand it myself, so, I think I am in the good way !!!!!

I do prefer answer by Email Pse

THANKS A LOT

/EX

Message-ID: <199705311330.JAA28675@erinet.com>
Source record: 93644

The Realistic TRC-415 uses a LC7132 PLL which is one of those not easily modifiable ROM based chips. The chip accepts direct VCO input in the range of 13-16 Mhz depending on whether you are in TX or RX. The 10.240 Mhz crystal is used as the reference for the PLL and for the second RX mixer.

In receive mode the T/R pin on the PLL is pulled high which selects a VCO division in the range of 3254 (Ch 1) to 3342 (Ch 40). The VCO generates a frequency in RX mode from 16.270 Mhz (Ch 1) to 16.710 Mhz (Ch 40). The 16 Mhz VCO is mixed with the 27 Mhz RF in the 1st RX mixer to give a first IF of 10.695 Mhz. The 10.695 Mhz IF is mixed with the 10.240 Mhz PLL reference crystal to give a second IF of 455 Khz.

In transmit mode the T/R pin on the PLL is pulled low which selects a VCO division in the range of 5393 (Ch 1) to 5481 (Ch 40). The VCO generates a frequency in TX mode from 13.4825 Mhz (Ch 1) to 13.7025 Mhz (Ch 40). The 13 Mhz VCO is then doubled to give a TX output in the 27 Mhz range. In TX mode a capacitor is placed in the VCO circuit to lower the VCO frequency from 16 Mhz RX mode to 13 Mhz TX mode.

Because the PLL accepts the direct VCO input (13 - 16 Mhz) and the channel selection is decoded by ROM in the PLL, this radio is not easily modifiable and changing the 10.240 Mhz crystal is NOT the way to go!

I didn't get your original message so I don't have your email address, so maybe someone that does have your original message will forward this message on to you.

Regards,

Phil

Check the Uof Aloberta cookbook

at ftp://nyquist.ee.ualberta.ca/pub/cookbook/comp/parallel/

you have two or three files for steppers like the 3axis file

FAR is still in business, he was at Dayton. Perhaps that's when you called.
As you know, FAR is a one man show, and getting ready for, and going to, Dayton
probably caused everything else to be shutdown for the duration.
